## PREFACE

THE purpose of this book is to give the theory of Mathieu functions and to demonstrate its application to representative problems in physics and engineering science. It has been written for the technologist, and *is not addressed in any sense to the pure mathematician*, for whom I am not qualified to write. Between the outlook of the two parties lies a gulf as wide as that between sinner and saint or vice versa! Although, by virtue of necessity, the technologist may occasionally deviate from the narrow path followed rigorously by the pure mathematician, it must not be forgotten that the consequences of such deviation may be practical results of considerable benefit to the community at large. Since the pure mathematician profits by these technological advances, any criticisms of methods used by the technologist should be entirely of a *constructive and helpful* nature.

The text is in two parts, (1) Theory, (2) Applications; but there is no need to peruse the whole of (1) before reading (2). For instance a study of the second half of Chapter IV will enable the reader to cope with most of the applications in Chapter XV. Some theory is associated with computation of parameters, and of coefficients in series. Other parts of it, not applied directly, are included in the hope that future needs will be met. The reader is expected to have an elementary knowledge of (a) Bessel functions, because they play an important role in Chapters VIII, X, XI, XIII, XVII-XVIII; (b) convergence of infinite series and integrals, and the consequences of uniform convergence, e.g. continuity of a function, term-by-term differentiation and integration of series. If these subjects are unknown, the requisite knowledge should be acquired [202, 214, 215, 218].

The chapter sequence is such as to reduce forward references to a minimum; unfortunately they are unavoidable. The original memoirs from which information was taken are indicated in [ ], which denotes the number in the reference list on pp. 373-81. The analysis herein is seldom the same as that in the original memoir. In writing the manuscript I realized that there were wide gaps which, if left unfilled, would have rendered the text discontinuous. The filling of these gaps has entailed considerable labour; in fact more than one-third of the text is new. The main part of it is in 'Additional

Results', and in Chapters IV, V, VII–XI, XIII, XIV, XVII, Appendixes I, III. The new method of computing the coefficients in the periodic part of the series representation of  $fe_m$ ,  $ge_m$ ,  $Fe_m$ ,  $Ge_m$  in Chapter VII is a joint contribution with W. G. Bickley.

*Symbolism.* The variety of notations encountered in the literature on the subject, the introduction of new forms of solution, new multipliers, etc., necessitated a careful survey of and a decision on notation. The first item for consideration was the form to be taken by Mathieu's equation. The canonical form chosen is

$$\frac{d^2y}{dz^2} + (a - 2q \cos 2z)y = 0, \quad (1)$$

More than two years after this decision had been made, H. Jeffreys pointed out that the form used by Mathieu in his original memoir [130] was

$$\frac{d^2P}{d\alpha^2} + (R - 2h^2 \cos 2\alpha)P = 0. \quad (2)$$

Thus after encircling the point at issue for about three-quarters of a century and encountering many branches, we have at last returned (quite unwittingly) to the initial or starting value! The coincidence seems significant. If we take  $k = +q^{\frac{1}{2}}$ , the arguments in the Bessel series solutions of (1), and its three other forms, have no fractional factors. Symbols used for various classes of solution have been selected to avoid confusion with other mathematical functions. The basis of the notation is 'e' for elliptic cylinder function, introduced by E. T. Whittaker some thirty-five years ago. He used  $ce$ ,  $se$ , to signify 'cosine-elliptic', 'sine-elliptic', and associated Mathieu's name with these periodic functions. Herein the generic designation 'Mathieu function' applies to all solutions of (1) in its four forms, which have the appropriate multipliers and/or normalization. The functions are classified, for  $q$  real, in Appendix III. For second (non-periodic) solutions of (1) which correspond to  $ce_m(z, q)$ ,  $se_m(z, q)$ , the letters  $f$ ,  $g$  are used. Thus the respective second solutions are written  $fe_m(z, q)$ ,  $ge_m(z, q)$ . When  $iz$  is substituted for  $z$  in  $ce_m(z, q)$ , etc., we follow H. Jeffreys [104] and use capital letters. Accordingly we have  $Ce_m(z, q)$ ,  $Se_m(z, q)$ ,  $Fe_m(z, q)$ ,  $Ge_m(z, q)$ . There are also second solutions involving the  $Y$ - and  $K$ -Bessel functions, which take precedence over the two latter. They are designated  $Fey_m(z, q)$ ,  $Gey_m(z, q)$ ,  $Fek_m(z, q)$ ,  $Gek_m(z, q)$ .  $Fey_m(z, q)$  is a *particular* linear combination of the even

first solution  $ce_m(z, q)$ , and the corresponding odd solution  $fe_m(z, q)$  of (1), in which  $z$  is replaced by  $iz$ . For wave propagation problems, combination solutions akin to the Hankel functions have been introduced. They have been allocated the symbols Me, Ne, M being for Mathieu and N the next letter of the alphabet. Owing to the war, it was not till the summer of 1946 that, as a result of correspondence with G. Blanch, I became aware that in references [23, 211] Stratton, Morse, Chu, and Hutner had defined functions represented by series of  $Y$ -Bessel functions (similar to some in Chapter VIII), and also combination functions akin to Me, Ne.

The Mathieu functions of positive integral order are solutions of (1) in its four forms when the parametric point  $(a, q)$  lies *upon* one of the characteristic curves  $a_m, b_m$  of Figs. 8 and 11. The functions of fractional order, namely,  $ce_{m+\beta}(z, q), se_{m+\beta}(z, q), 0 < \beta < 1$ , have been introduced to provide standard solutions when  $(a, q)$  lies *within* a stable region of Figs. 8, 11. If  $\beta = p/s$ , a rational fraction, *always* presumed to be in its lowest terms, the functions are periodic in  $z$  real, with period  $2s\pi, s \geq 2$ . The functions  $ceu_{m+\mu}(\pm z, q)$  have been introduced to provide standard solutions when  $(a, q)$  lies *in* an unstable region of Figs. 8, 11.  $\mu$  is real and positive, and 'u' signifies that the solution pertains to an unstable region. If  $q$  is negative imaginary,  $ce_m(z, q)$  is a complex function of  $z$ , so in Chapter III,  $cer_m z$  and  $cei_m z$ , have been used to denote its real and imaginary parts, respectively. Symbols in heavy type signify 'per unit area', or 'per unit length';  $m, n, p, s$  usually represent positive integers including zero, except in §§ 3.40–3.51 where  $s$  is real and positive;  $r$  represents any integer;  $\simeq$  means 'approximately equal to';  $\sim$  signifies 'asymptotically equal to', 'approaches asymptotically to', or 'asymptotic form';  $R(z), \text{Im}(z)$  or  $\text{Imag}(z)$ , indicate the real and imaginary parts of  $z$ , respectively; superscripts in  $A_{2r+1}^{(2n+1)}, B_{2r+2}^{(2n+2)}$  signify the order of the function, while the subscripts denote that of the coefficient itself; the subscripts in  $a_m, b_m, a_{m+\beta}$  indicate the order of the function of which  $a_m$ , etc., is the characteristic number. Wherever possible a standard summation from 0 to  $+\infty$  is used. Other symbols employed are those generally found in advanced mathematical texts in English. References to Fig. 8 are to either 8A or 8B, whichever is the more convenient.

*Tables.* The values of the characteristic numbers  $a_0, \dots, a_5; b_1, \dots, b_6$ , computed by Ince, and abbreviated by him to 7 decimal places [95],

are given in Appendix II for the range  $q = 0$  to 40. For  $q$  imaginary, some  $a_0$  computed by Goldstein and Mulholland are given in Table 4, p. 51 [57]. No other tabular values are reproduced, since they are much too extensive for inclusion here. An interpolable table of  $a_0, \dots, a_{15}$ ;  $b_1, \dots, b_{15}$ , for the range  $q = 0$ –25, compiled by the National Bureau of Standards Mathematical Tables Project, became available after completion of the manuscript. By its aid, the stability chart of Fig. 8A may be extended considerably for  $a$  positive. To obtain a more uniform vertical spacing ( $a$ -axis),  $a^\dagger$  should be plotted instead of  $a$ . There are no tabular values of  $Ce_m$ ,  $Se_m$ ,  $Fey_m$ ,  $Gey_m$ ,  $Fek_m$ ,  $Gek_m$ , and this restricts the use of Mathieu functions in applications. Functions of integral order suitable for tabulation are listed in reference 8. To the list may be added an interpolable table of  $a$ ,  $a^\dagger$ ,  $q$ ,  $\beta$ ,  $\mu$ . This would enable a *large* iso- $\beta\mu$  chart akin to Fig. 11 (but much extended) to be plotted using different coloured inks, thereby rendering visual interpolation possible. If, as mentioned above,  $a^\dagger$  is plotted instead of  $a$ , the interpolation is approximately linear when  $|q|$  is not too large. A chart of this type would be of inestimable value for solving Mathieu equations.

*Acknowledgements.* Prof. W. G. Bickley and Mr. T. Lewis undertook the arduous task of reading much of the manuscript. To them I express my sincere thanks for help and advice which has been invaluable. I am indebted to Prof. Bickley for additional terms in (2), (4), (6) § 2.151. My thanks are also due to Prof. T. A. A. Broadbent and Dr. J. C. P. Miller for criticizing certain sections of the manuscript. I take this opportunity of thanking Dr. Gertrude Blanch for pointing out the relations in § 4 of the additional results. She obtained (1)–(6) § 3, and (1), (2) § 8 independently. The whole of the proofs have been read and the analysis checked by Messrs. T. V. Davies and A. L. Meyers. To them I tender my best thanks for the meticulous care which they have exercised, and for their valuable suggestions. I am much indebted to Dr. L. J. Comrie for the loan of books and reprints of papers; also to him and Miss Dorothy Reynolds for checking some of the calculations in Chapter VI, and for computing the numerical data, using analysis in Chapter V, from which the important iso- $\beta\mu$  chart of Figure 11 was plotted. Sir Edmund T. Whittaker kindly loaned me a large number of reprints of papers by various authors, while Mrs. P. Ince kindly gave me copies of the late Prof. E. L. Ince's published works. Prof. A. L. Dixon,

Drs. John Dougall, I. M. H. Etherington, Harold Jeffreys, and Miss Ethel M. Harris were good enough to loan me books and memoirs, which I would not have seen otherwise.

It is with pleasure that I acknowledge permission to reproduce the following diagrams and tables in the text:

1. Table 4; *Philosophical Magazine*; paper by S. Goldstein and H. P. Mulholland [57].
2. Figs. 10 A, B; Institute of Radio Engineers (America); paper by F. Maginniss [123].

## HISTORICAL INTRODUCTION

THE majority of functions used in technical and applied mathematics have originated as the result of investigating practical problems. Mathieu functions were introduced by their originator in 1868 [130], when he determined the vibrational modes of a stretched membrane having an elliptical boundary. The two-dimensional wave equation

$$\frac{\partial^2 V}{\partial x^2} + \frac{\partial^2 V}{\partial y^2} + k_1^2 V = 0 \quad (1)$$

was transformed to elliptical (confocal) coordinates, and then split up into two ordinary differential equations. If  $q^{\frac{1}{2}} = \frac{1}{2}k_1 h$ ,  $h$  being the semi-interfocal distance, and  $a$  an arbitrary separation constant, the equations take the form

$$\frac{d^2 v}{dz^2} + (a - 2q \cos 2z)v = 0, \quad (2)$$

$$\frac{d^2 v}{dz^2} - (a - 2q \cosh 2z)v = 0, \quad (3)^\dagger$$

$$\text{i.e.} \quad \frac{d^2 v}{d(iz)^2} + (a - 2q \cos 2zi)v = 0. \quad (4)$$

In Mathieu's problem the parameters  $a$ ,  $q$  were real.

It is evident that (3), the second of the two equations into which (1), expressed in elliptical coordinates, was resolved, may be derived from (2) by writing  $\pm zi$  for  $z$ , and vice versa. This reciprocal relation is sometimes considered to be a fluke! Equations (2), (3) will be regarded herein as the Mathieu and modified Mathieu equations respectively, for  $q > 0$ . For the elliptical membrane problem, the appropriate solutions of equation (2) are called (ordinary) Mathieu functions, being periodic in  $z$  with period  $\pi$  or  $2\pi$ . As a consequence of this periodicity,  $a$  has special values called characteristic numbers. The corresponding solutions of (3), for the same  $a$  as in (2), are known as *modified* Mathieu functions,  $\ddagger$  being derived from the ordinary type

$\dagger$  In reference [103] this is termed the 'modified Mathieu equation'.

$\ddagger$  Some writers refer to them as 'associated' functions, and others as 'hyperbolic' Mathieu functions. They could be designated Mathieu functions of imaginary argument. In view of the analogy with the derivation of the modified Bessel functions  $I$ ,  $K$ , the term 'modified' seems to be preferable. Also Ince in [85] uses the word 'associated' to define an entirely different set of functions.

by making the argument imaginary. The second independent sets of solutions for the same  $a$  are not needed in the membrane problem. They are non-periodic, and those for (2) tend to infinity with  $z$  real. Sometimes the solutions of (2), (3) are designated elliptic and hyperbolic cylinder functions, respectively, just as the  $J$ -,  $Y$ -Bessel functions are termed (circular) cylinder functions.

Following the appearance of Mathieu's work, some ten years elapsed before anything further was published on the subject. In *Kugelfunktionen* [196] Heine (1878) defined the first solutions of integral order of (2) by cosine and sine series, but the coefficients were not calculated. These series fulfil the conditions for Fourier series, but the coefficients are not obtained by integration in the usual way. They have been called Fourier series by many authors. Heine also gave a transcendental equation for the characteristic numbers, pertaining to the first solutions, in the guise of an infinite continued fraction. This form was used to great advantage about half a century later by Goldstein [52], and by Ince [88, 92, 93], for computing the characteristic numbers and the coefficients in the series. Heine also demonstrated that one set of periodic functions of integral order could be expanded in a series of Bessel functions.

G. W. Hill, in a celebrated memoir, investigated the 'Mean motion of the Lunar Perigee' [70] by means of an extended or generalized form of Mathieu equation, namely,

$$\frac{d^2y}{dz^2} + [a - 2q\psi(2z)]y = 0, \quad (5)$$

where in Hill's case  $-2q\psi(2z) = 2[\theta_2 \cos 2z + \theta_4 \cos 4z + \dots]$ ,  $a = \theta_0$ , the  $\theta$  being known parameters. The work, done in 1877, was published in 1886. The subject of infinite determinants was introduced into analysis for the first time, and Hill's name is now associated with an equation of form (5).

In 1883 G. Floquet published a general treatment of linear differential equations with periodic coefficients, of which Mathieu's and Hill's equations are cases in point [49]. Lord Rayleigh studied the classical Melde† experiment by aid of Hill's analysis in 1887 [155, 207]. He also dealt with the problem of wave propagation in stratified media, and the oscillations of strings having a periodic distribution of mass [155]. In Melde's experiment one end of a hori-

† *Pogg. Ann.* **109**, 193, 1860.

zontal thread is fixed, the other being attached to the prong of a massive low-frequency tuning-fork mounted vertically. When the fork moves along the thread, and the tension is suitably adjusted, the thread vibrates at right angles to its length, i.e. transversely, at a frequency *one-half that of the fork*. As we shall see in due course, this *sub-harmonic* of half-frequency is consistent with the periodic solutions of equation (2), of odd integral order, whose period is  $2\pi$ .

In 1894 Tisserand [213] showed how the solution of (5) could be obtained in the form of a Maclaurin expansion. He also described Lindstedt's method of solving (2) by aid of continued fractions, the convergence of which was investigated by H. Bruns [17]. The theory of Mathieu functions was extended by E. Särchinger in that year [158].

The first appearance of an asymptotic formula for the modified functions in 1898 was due to R. C. Maclaurin [122]. Some years later W. Marshall published a different but more detailed analysis [128]. Neither of these authors obtained the constant multipliers, which are indispensable in numerical work. In 1922, however, Marshall produced the multiplier for his series [129]. D. Hilbert discussed characteristic values and obtained an integral equation, with a discontinuous nucleus, for the periodic solutions of (2) in 1904 [69]. The theory of the functions was treated in certain respects by S. Dannacher in 1906 [26], while W. H. Butts extended the treatment and computed some tabular values in 1908 [19]. In that year B. Sieger published an important paper on the diffraction of electromagnetic waves by an elliptical cylinder. Amongst other topics he dealt with orthogonality, and developed integral equations by means of which he reproduced Heine's solutions in Bessel function series. Using an integral equation with a different nucleus, he derived a solution of equation (3) as a series of Bessel function products, and discussed its convergence [162]. This paper does not seem to have been known to British authors, whose contributions after 1908 sometimes cover similar ground.

It appears that, apart from Sieger's paper, the subject attracted but scant attention in the period 1887–1912, owing possibly to a dearth of physical applications, and to analytical difficulties; for the Mathieu functions cannot be treated in a straightforward way like Bessel or Legendre functions. In 1912, however, E. T. Whittaker started the first systematic study of the subject by a paper read before the International Congress of Mathematicians [184]. Therein

he gave an integral equation for one set of the periodic functions of integral order. A similar equation for the modified functions was published in 1908 by Sieger (*supra*), and Whittaker was obviously unaware of this. Next year (1913) Whittaker published a new method of obtaining the general solution of (2) when  $a$  is not a characteristic number for a function of integral order [186]. Using this method as a basis, A. W. Young, one of Whittaker's pupils, gave a treatment of general solutions and discussed the question of their stability, i.e. whether the solution tends to zero or to infinity as  $z \rightarrow +\infty$  [191]. Recurrence formulae for the Mathieu functions cannot be deduced by the direct procedure used for functions of hypergeometric type, e.g. Bessel and Legendre functions. Whittaker, however, evolved a new method, and in 1928 applied it to obtain recurrence relations for the modified Mathieu functions [187].

From 1915 till his early decease in 1941, the chief contributor to the subject was E. L. Ince, a pupil of Whittaker. During this period he published eighteen papers on Mathieu functions and cognate matters. In his first paper (1915) he obtained the second non-periodic solution of equation (2) when  $a$  is a characteristic number for a function of period  $\pi$ ,  $2\pi$ , this being the first solution [80]. Following this he treated Hill's equation on the lines of [186], and obtained formulae different in character from those given by Hill [81–3]. Many aspects of the subject, including characteristic numbers, periodicity, zeros, were covered [87–97]. He introduced the stability chart (Fig. 8A) for functions of integral order in 1925 [88]. The culminating point was perhaps his almost single-handed feat in calculating the characteristic numbers, coefficients in the cosine and sine series for the first solutions of integral order, zeros of these functions, turning-points and values of the functions. The tables occupy some sixty pages of print and appeared in 1932 [95, 96].

A general study of Mathieu's equation was made by J. Dougall in three papers published between 1916 and 1926 [36–8]. As well as a general solution, he obtained asymptotic expansions for the modified functions with large  $z$ , and a contour integral which, under certain conditions, degenerates to one for the  $J$ -Bessel function. Unaware of Sieger's work in 1908, Dougall derived a solution in terms of Bessel function products. The method of derivation was different from that of Sieger.

Until 1921 the only known periodic solutions of Mathieu's equa-

tion (2) had period  $\pi$  or  $2\pi$ . In that year E. G. C. Poole generalized the position and showed that with appropriate values of  $a$  for an assigned  $q$ , (2) would admit solutions having period  $2s\pi$ ,  $s$  being an integer  $\geq 2$  [150]. These solutions *coexist* and their sum, with the usual arbitrary constant multipliers, constitutes a fundamental system. About the same time Ince proved that two solutions of period  $\pi$  or  $2\pi$  could not coexist (for the same  $a$ ,  $q$ ), i.e. if the first solution had period  $\pi$  or  $2\pi$ , the second would be non-periodic [84]. A different proof of this was given a few years later by Z. Markovic [126]. He introduced some new integral equations of Volterra type in 1925 [127].

The second solution of (2),  $a$  being a characteristic number for a periodic function (first solution) of integral order, was studied by S. Dhar in 1921 using a method different from that of Ince [30]. Dhar's publications from 1921 to 1928 cover various aspects of convergence, and integral equations for the second solution [29–35]. Using expansions in Mathieu functions (ordinary and modified), he reproduced Rayleigh's formula† for the diffraction of electromagnetic waves due to a long metal cylinder of elliptical cross-section [193]. In 1922 P. Humbert discussed a modified form of Mathieu equation,‡ whose solutions he called 'Mathieu functions of higher order'. He showed the relation between these and the Gegenbauer polynomials [79].

It often happens that the zeros of functions which occur in practical applications are essential in connexion with boundary conditions. The solution for a vibrating circular membrane is expressed in terms of  $J$ -Bessel and circular function products. The zeros of the Bessel functions determine the vibrational pulsataces and location of the nodal circles, while those of the circular functions define the positions of the nodal radii. In the case of an elliptical membrane, the solution is expressed in terms of modified and ordinary Mathieu function products. The zeros of the modified functions determine the vibrational pulsataces and confocal nodal ellipses, while those of the ordinary functions define a system of confocal nodal hyperbolae. When the eccentricity of the bounding ellipse tends to zero, the nodal ellipses tend to become nodal circles, and the nodal hyperbolae tend to nodal radii. Analytically, apart from constant multipliers, the

; *Phil. Mag.* **44**, 28, 1896. The analysis in Rayleigh's paper is devoid of Mathieu functions.

† Not equation (3).

modified Mathieu functions tend to  $J$ -Bessel functions of the same order, and the ordinary functions tend to circular functions.

In 1923 E. Hille published a lengthy discourse on zeros and cognate matters. He also gave another proof of the non-periodic nature of the second solution of (2), when  $a$  is a characteristic number for the first solution of period  $\pi$  or  $2\pi$  [71]. A table of zeros of eight of these latter functions was published by Ince in 1932 [96]. At the time of writing, there is no table of zeros of the modified functions, but formulae are given herein from which the larger zeros may be computed.

During recent years the problem of frequency modulation in radio transmission has assumed importance, in particular since the frequency was raised to 45 megacycles per second or more. The subject was studied analytically by J. R. Carson in 1922, who dealt with the simple case of a resistanceless oscillatory electrical circuit having a periodically varying capacitance. An approximate differential equation for a circuit with capacitance  $C(t) = C_0 + C_1 \cos 2\omega t$ , where  $C_1 \ll C_0$ , is a Mathieu type. Values of the circuit parameters were such that the solution could, with adequate approximation, be expressed as a series of circular functions whose coefficients were  $J$ -Bessel functions. These coefficients give the relative amplitudes of the 'side-band frequencies' on each side of the central or 'carrier frequency'. The latter is said to be 'frequency-modulated' [21].

In 1934 A. Erdélyi studied the problem above, when the circuit contained resistance. Solutions were obtained for stable and unstable cases, by aid of integral equations. Both solutions were better approximations than that of Carson, and revealed the fact that 'amplitude modulation' of the 'carrier' occurs as well as 'frequency modulation' [44].

In 1936 Erdélyi obtained a solution of equation (3) by aid of the Laplace integral. He derived another form of asymptotic expansion and gave relationships of the type  $y_1(ze^{i\mu\pi}) = e^{i\mu\pi} y_1(z)$ ,  $\mu = ni$ ,  $n$  an integer [47].

In the period 1932–6 W. L. Barrow treated problems on electrical circuits with periodically varying parameters, both analytically and experimentally [2, 3, 4].

Sometimes in applications the parameters of a differential equation are such that it lends itself to approximate methods of solution. In 1923 H. Jeffreys gave an analysis pertaining to approximate solutions of (3). He also obtained asymptotic formulae. The results were

applied in an investigation of the vibrational modes of water in a lake whose plan view is elliptical, this problem being of special interest in hydrodynamics. Numerical data were obtained for a number of the lower modes, their periods and the tide heights being computed [101-4].

The making of numerical tables usually receives little encouragement, while the thanks offered by the user are parsimonious rather than plentiful. We have already referred to Ince's philanthropic gesture in computing tabular values. In 1927 S. Goldstein published the results of extensive work on Mathieu functions, and included a set of tables for five of the periodic functions of integral order [52]. Following Heine and Sieger the tabulated functions are defined as sine and cosine series, the coefficients and the characteristic numbers being given for a wide range of  $q$ . A new and acceptable normalization of the functions was adopted, this being based upon their orthogonal properties. The same publication contained additional integral equations (akin to those of Sieger and Whittaker), some asymptotic expansions for  $z$  large and  $q$  large (complete with multipliers), an asymptotic formula for the characteristic numbers,<sup>†</sup> and formulae for the larger zeros in  $q$  of the modified functions. There is also a general discussion relating to the second solution and an extension of Heine's expansions in Bessel function series, the  $I$ -type being introduced. In additional papers Goldstein extended Jeffreys's investigation on elliptical lakes, and his own researches on characteristic numbers [53-7].

The problem of eddy currents in a straight conductor of elliptical cross-section was investigated by M. J. O. Strutt in 1927 [167]. He assumed constant current density at the surface. As this is untrue in practice, his analysis is mainly of academic interest. In common with other boundary-condition problems, the wave equation expressed in elliptical coordinates is separable into two Mathieu equations like (2), (3), but in the above problem  $q$  is negative imaginary. Strutt has solved a variety of technical problems involving Mathieu functions, e.g. diffraction of plane waves at a slit [173]. In 1929 he published a detailed study of the characteristic exponent  $\mu$  in Hill's equation (5) [171]. A list of his other works will be found in the references at the end of the book.

<sup>†</sup> Identical with that found independently by Ince using a different procedure [92, 93].

When experimenting with a moving-coil loud-speaker in 1925, the author found that under certain conditions the coil, although actuated by a sinusoidal current, *moved out of the magnetic field of the magnet*. The analysis, published in 1933, involved a Mathieu equation. Its solution for the axial displacement of the coil was characterized by a dominant term having a period much greater than that of the driving current. Reduction in amplitude of the latter resulted in an increase in the period of the dominant term, and vice versa [201].

Oseen's approximate differential equation is familiar in hydrodynamics. As might be anticipated from this equation, calculation of the vorticity in a viscous fluid flowing past a very long elliptical cylinder in its path necessitates the use of Mathieu functions. This subject was studied by M. Ray in 1936 [154], and by D. Meksyn in 1937 [137]. In 1938 T. Lewis published a general treatment of the problem of circular and elliptical cylinders, and a flat plate in a viscous fluid [116]. He showed that the solution given by Meksyn required modification to avoid infinite circulation of fluid. In 1941 T. V. Davies made a detailed study of the flat plate using modified Mathieu functions, whose behaviour he investigated in the neighbourhood of the origin [28].

About fifty years ago, the transmission of electromagnetic waves within hollow metal cylinders was contemplated by J. J. Thomson.† O. J. Lodge‡ verified the theory qualitatively using a hollow metal cylinder having a spark gap and transmitter at one end, the other being open. Three years later Lord Rayleigh§ showed that there was a plurality of modes in which electromagnetic waves could be transmitted within a perfectly conducting uniform circular tube of unlimited length. Using modern electronic devices, it is comparatively easy to incite the transmission modes of lower order within a hollow metal cylinder, now called a 'wave guide'. No cylinder is perfectly circular, so to ascertain the influence of deviation from circularity, L. J. Chu in 1938 investigated the propagation of electromagnetic waves within a hollow cylinder of elliptical cross-section. As might be expected, the final result entailed products of ordinary and modified Mathieu functions of integral order, the former having period  $\pi$ ,  $2\pi$  [22].

† *Recent Researches* (1893).

§ *Phil. Mag.* 43, 125, 1897.

‡ *Proc. Roy. Institution*, 14, 321, 1894.

In 1940 W. G. Bickley published new solutions of (3) with  $q < 0$ , these being expressed as expansions in  $I$ - and  $K$ -Bessel functions [6]. He also gave integral and asymptotic formulae for these solutions. During the same year J. G. Brainerd and C. N. Weygandt published data regarding general solutions of equation (2), when  $a$  is *not* a characteristic number for functions of integral order. The data were given up to  $z = 0.3\pi$ , using the Maclaurin method of solution (see § 4.40), with terms as far as  $y^{(21)}(0)$ . Beyond  $z = 0.3\pi$  the solutions, given in the form of curves, were extended by alternative means [12].

In 1943 S. Lubkin and J. J. Stoker applied Mathieu equations to investigate the stability of columns subjected to a steady pull with a periodically varying force superimposed [121].

What precedes is merely a brief survey of salient matters relating to Mathieu functions and their applications to technical problems. The work of other authors, too extensive to be examined in detail, is given in titular form in the list of references on pp. 373–81.

The occurrence of Mathieu functions in practical applications may be divided into two main categories. First there are the boundary-condition problems arising from solution of the two-dimensional wave equation (1), when expressed in elliptical coordinates. As stated previously, this yields a pair of Mathieu equations like (2), (3).† The appropriate solution of (2) is usually a periodic Mathieu function of integral order, while that of (3), in the cases of the elliptical membrane and the wave guide, is obtained by making the argument of this solution imaginary. Secondly there are what may be regarded as initial-value problems, in which only one equation like (2) is involved. Usually  $a$  is not then a characteristic number for a function of integral order having period  $\pi$  or  $2\pi$ , and the solution is general in type. It may (a) have period  $2s\pi$ ,  $s$  an integer  $\geq 2$ , (b) be non-periodic but bounded as  $z \rightarrow +\infty$ , (c) be non-periodic but unbounded as  $z \rightarrow +\infty$ . Frequency modulation and the moving-coil loud-speaker (see Chap. XV) are examples of the class of problem in question. The majority of applications, to date, pertain to the first category and involve the wave equation.

† In the analysis of Melde's experiment, the differential equation is in  $x$  and  $t$  coordinates, the solutions of the two resulting equations being circular functions in  $x$ , and periodic Mathieu functions of integral order in  $t$ .

# PART I

## THEORY OF MATHIEU FUNCTIONS

### II

#### FUNCTIONS OF INTEGRAL ORDER

**2.10. Canonical form of Mathieu's equation.** In solving the problem of the elliptical membrane [130], Mathieu obtained a differential equation of the type

$$\frac{d^2y}{dz^2} + (a - 2q \cos 2z)y = 0. \quad (1)$$

We shall regard this as the canonical form—ruled by general usage—of the equation. At times it may be expedient to replace  $+q$  by  $k^2$ . The parameters  $a$ ,  $q = k^2$ , will be limited to real numbers, unless stated otherwise, but  $z$  is usually unrestricted. The equation is a particular case of a linear type of the second order with periodic coefficients. Its solution takes different forms according to the values of  $a$ ,  $q$ . For the present we shall confine our attention to solutions having period  $\pi$  or  $2\pi$  in  $z$ . In the membranal problem, the displacement from the equilibrium position is a periodic function of one of the coordinates.† Thus if  $q$  is assigned,  $y$  will have period  $\pi$  or  $2\pi$  in  $z$ , provided  $a$  has one of an infinite sequence of particular numbers.

**2.11. Solution of (1) § 2.10 when  $q = 0$ .** Under this condition the equation becomes

$$\frac{d^2y}{dz^2} + ay = 0, \quad (1)$$

and it is convenient that the solution of (1) § 2.10 should then reduce to  $\cos mz$  or  $\sin mz$ . Accordingly we put  $a = m^2$ ,  $m = 1, 2, 3, \dots$ , thereby obtaining the pairs of distinct solutions  $+\cos z$ ,  $+\sin z$ ;  $+\cos 2z$ ,  $+\sin 2z$ ; and so on. When  $m = 0$ , we take the respective solutions to be  $+1$ ,  $0$ . Also *until* and *unless* stated otherwise, we shall adopt the convention that the coefficient of  $\cos mz$  and  $\sin mz$  is unity for all  $q$  [130].

† For a circular membrane the displacement at any radius depends upon  $\frac{\cos(m\theta)}{\sin(m\theta)}$  and is, therefore, a periodic function of  $\theta$  [202, p. 27]. The displacement of an elliptical membrane is periodic in the elliptical coordinate  $\eta$  ( $z$  in (1)), as shown in § 16.11.

**2.12. Dependence of  $a$  upon  $q$  for a periodic solution.** When  $q \neq 0$ ,  $a$ ,  $q$  must be interrelated for the solution of (1) § 2.10 to have period  $\pi$  or  $2\pi$ , so  $a$  is a function of  $q$ . If we write

$$a = m^2 + \alpha_1 q + \alpha_2 q^2 + \alpha_3 q^3 + \dots, \quad (1)$$

the desired form  $a = m^2$  is obtained when  $q = 0$ , and the equation then reduces to

$$\frac{d^2 y}{dz^2} + m^2 y = 0, \quad (2)$$

whose solutions are  $\pm \cos mz$ ,  $\pm \sin mz$ . Conventionally we adopt a *positive* sign.

**2.13. Periodic solution of the first kind.** To illustrate *one* method of finding a particular periodic solution of (1) § 2.10, we take the case where  $a = m^2 = 1$  when  $q = 0$ . Then by (1) § 2.12 we have for  $q \geq 0$

$$a = 1 + \alpha_1 q + \alpha_2 q^2 + \alpha_3 q^3 + \dots \quad (1)$$

Since the solution is to reduce to, say,  $\cos z$  when  $q$  vanishes, we assume that

$$y = \cos z + q c_1(z) + q^2 c_2(z) + q^3 c_3(z) + \dots, \quad (2)^\dagger$$

$c_1, c_2, \dots$  being functions of  $z$  to be determined. Substituting (2) into (1) § 2.10 and using the value of  $a$  from (1) above, we get

$$\left. \begin{aligned} y'' &= -\cos z + q c_1'' + q^2 c_2'' + q^3 c_3'' + \dots, \\ ay &= \cos z + q(c_1 + \alpha_1 \cos z) + q^2(c_2 + \alpha_1 c_1 + \alpha_2 \cos z) + \\ &\quad + q^3(c_3 + \alpha_1 c_2 + \alpha_2 c_1 + \alpha_3 \cos z) + \dots, \\ -(2q \cos 2z)y &= -q(\cos z + \cos 3z) - 2q^2 c_1 \cos 2z - \\ &\quad - 2q^3 c_2 \cos 2z - \dots \end{aligned} \right\} \quad (3)$$

Equating coefficients of like powers of  $q$  to zero gives

$$q^0 \quad \cos z - \cos z \equiv 0, \quad (4)$$

$$q \quad c_1'' + c_1 - \cos 3z + (\alpha_1 - 1)\cos z = 0, \quad (5)$$

of which the particular integral corresponding to  $(\alpha_1 - 1)\cos z$  is the

† In ref. [158] it is shown that the solutions of Mathieu's equation, having period  $\pi$  or  $2\pi$  consist entirely of cosine or sine terms, and not a combination of the two. In ref. [223] it is shown that if one solution is even, the other must be odd. Thus two independent even or two independent odd solutions cannot occur. The only singularity of (1) § 2.10 is an essential one at infinity due to  $\cos 2z$ . Hence every solution is an integral function of  $z$ .

non-periodic function  $\frac{1}{2}(1-\alpha_1)z \sin z$ . Since  $y$  is to be periodic, this term must vanish, so

$$\alpha_1 = 1, \quad (6)$$

while

$$c_1'' + c_1 = \cos 3z. \quad (7)$$

Now the particular integral of  $v'' + v = A \cos mz$  is  $-A \cos mz/(m^2-1)$  ( $m \neq 1$ ), so with  $A = 1$  and  $m = 3$ ,

$$c_1 = -\frac{1}{8} \cos 3z. \quad (8)$$

Inclusion of  $\frac{\sin}{\cos} z$  [complementary function of (7)] in (8) would involve a term in  $q \frac{\sin}{\cos} z$  in the solution. By § 2.11 the coefficient of  $\cos z$  is to be unity for all  $q$ ; also  $\sin z$  is odd. Hence the C.F. of (7) and subsequent equations is omitted.

$$q^2 \quad c_2'' + c_2 + \alpha_1 c_1 - 2c_1' \cos 2z + \alpha_2 \cos z = 0. \quad (9)$$

Substituting for  $\alpha_1, c_1$  from (6), (8) and expressing  $\cos 2z \cos 3z$  as a sum of two cosines, we get

$$c_2'' + c_2 - \frac{1}{8} \cos 3z + \frac{1}{8} \cos 5z + \left(\frac{1}{8} + \alpha_2\right) \cos z = 0. \quad (10)$$

As before, the particular integral pertaining to  $(\frac{1}{8} + \alpha_2) \cos z$  is non-periodic, so

$$\alpha_2 = -\frac{1}{8}, \quad (11)$$

while

$$c_2'' + c_2 = \frac{1}{8} \cos 3z - \frac{1}{8} \cos 5z. \quad (12)$$

By aid of the general formula above, the particular integral is

$$c_2 = -\frac{1}{64} \cos 3z + \frac{1}{192} \cos 5z. \quad (13)$$

Proceeding in this way leads to the results:

$$\alpha_3 = -\frac{1}{64}, \quad c_3 = -\frac{1}{512} \left( \frac{1}{3} \cos 3z - \frac{4}{9} \cos 5z + \frac{1}{18} \cos 7z \right), \quad (14)$$

$$\alpha_4 = -\frac{1}{1536},$$

$$c_4 = \frac{1}{4096} \left( \frac{11}{9} \cos 3z + \frac{1}{6} \cos 5z - \frac{1}{12} \cos 7z + \frac{1}{180} \cos 9z \right), \quad (15)$$

and so on.

Substituting for  $c_1, c_2, \dots$  in (2) gives a solution of Mathieu's

equation, periodic in  $z$ , with period  $2\pi$ . It is denoted by  $\text{ce}_1(z, q)^\dagger$  and represented by the series

$$\begin{aligned} \text{ce}_1(z, q) = & \cos z - \frac{1}{8}q \cos 3z + \frac{1}{64}q^2 \left( -\cos 3z + \frac{1}{3} \cos 5z \right) - \\ & - \frac{1}{512}q^3 \left( \frac{1}{3} \cos 3z - \frac{4}{9} \cos 5z + \frac{1}{18} \cos 7z \right) + \\ & + \frac{1}{4096}q^4 \left( \frac{11}{9} \cos 3z + \frac{1}{6} \cos 5z - \frac{1}{12} \cos 7z + \frac{1}{180} \cos 9z \right) + O(q^5). \quad (16) \end{aligned}$$

The value of  $a$  necessary to yield this solution is found by substituting the  $\alpha$  into (1). Then we get

$$a = 1 + q - \frac{1}{8}q^2 - \frac{1}{64}q^3 - \frac{1}{1536}q^4 + \frac{11}{36864}q^5 + O(q^6). \quad (17)$$

For a given  $q$ , the value of  $a$  found from (17) is called the *characteristic number* of the Mathieu function  $\text{ce}_1(z, q)$ . When  $q = 0$ ,  $a = 1$ , and the r.h.s. of (16) reduces to  $\cos z$ .

The notation  $\text{ce}_m(z, q)$  signifies a cosine type of Mathieu function of order  $m$ , which reduces to a multiple of  $\cos mz$  when  $q = 0$ . Since  $m$  may be any positive integer, there is an infinite number of solutions of type (16). These functions are even in  $z$ , being unchanged if  $-z$  is written for  $z$ .

**2.14. Another periodic solution of the first kind.** In accordance with our convention in § 2.11, if  $m^2 = 1$ , the second solution of (1) § 2.10 reduces to  $\sin z$  when  $q = 0$ . If we assume a solution

$$y = \sin z + qs_1(z) + q^2s_2(z) + q^3s_3(z) + \dots \quad (1)$$

and proceed as in § 2.13, we obtain a sine type of Mathieu function designated  $\text{se}_1(z, q)^\ddagger$ . Thus

$$\begin{aligned} \text{se}_1(z, q) = & \sin z - \frac{1}{8}q \sin 3z + \frac{1}{64}q^2 \left( \sin 3z + \frac{1}{3} \sin 5z \right) - \\ & - \frac{1}{512}q^3 \left( \frac{1}{3} \sin 3z + \frac{4}{9} \sin 5z + \frac{1}{18} \sin 7z \right) + \\ & + \frac{1}{4096}q^4 \left( -\frac{11}{9} \sin 3z + \frac{1}{6} \sin 5z + \frac{1}{12} \sin 7z + \frac{1}{180} \sin 9z \right) + O(q^5), \quad (2) \end{aligned}$$

<sup>†</sup> 'ce' is an abbreviation of 'cosine-elliptic', introduced by E. T. Whittaker.

<sup>‡</sup> 'se' is an abbreviation of 'sine-elliptic'.

provided

$$a = 1 - q - \frac{1}{8}q^2 + \frac{1}{64}q^3 - \frac{1}{1536}q^4 - \frac{11}{36864}q^5 + O(q^6). \quad (3)$$

This particular value of  $a$  is the *characteristic number* for the Mathieu function  $\text{se}_1(z, q)$ , periodic in  $z$  with period  $2\pi$ , which reduces to  $\sin z$  when  $q = 0$ . Since  $\text{se}_1(z, q) = -\text{se}_1(-z, q)$ , the function is odd in  $z$ .

FIG. 1. Graphs of  $ce_1(z, 2)$ ,  $ce_3(z, 2)$ ,  $ce_5(z, 2)$  over a period  $2\pi$ .

FIG. 2. Graphs of  $se_1(z, 2)$ ,  $se_3(z, 2)$ ,  $se_5(z, 2)$  over a period  $2\pi$ .

If in (16) § 2.13 we write  $(\frac{1}{2}\pi - z)$  for  $z$  and  $-q$  for  $q$ , (2) above is reproduced, and vice versa. Since the values of  $a$  differ for the two periodic functions  $ce_1$ ,  $se_1$ , these functions are not solutions of the same equation except when  $q = 0$ . The graphs of these functions for  $q = 2$  are shown in Figs. 1, 2.

**2.150. Periodic solution of (1) § 2.10 of order  $m$ .** To derive this, we assume for the cosine type of function that

$$y = \cos mz + qc_1(z) + q^2 c_2(z) + q^3 c_3(z) + \dots \quad (1)$$

and 
$$a = m^2 + \alpha_1 q + \alpha_2 q^2 + \alpha_3 q^3 + \dots \quad (2)$$

The solution obtained is either of the class  $ce_{2n}(z, q)$  or  $ce_{2n+1}(z, q)$ , according as  $m$  in (2) is even or odd. If  $m = 2$ , we find that

$$\begin{aligned} ce_2(z, q) = & \cos 2z - \frac{1}{8}q \left( \frac{2}{3} \cos 4z - 2 \right) + \frac{1}{384}q^2 \cos 6z - \\ & - \frac{1}{512}q^3 \left( \frac{1}{45} \cos 8z + \frac{43}{27} \cos 4z + \frac{40}{3} \right) + \\ & + \frac{1}{4096}q^4 \left( \frac{1}{540} \cos 10z + \frac{293}{540} \cos 6z \right) + O(q^5), \end{aligned} \quad (3)$$

with 
$$a = 4 + \frac{5}{12}q^2 - \frac{763}{13824}q^4 + \frac{10\ 02401}{796\ 26240}q^6 + O(q^8). \quad (4)$$

Then  $a$  reduces to 4 and  $ce_2$  to  $\cos 2z$  when  $q = 0$ , which is in accordance with our convention in § 2.11. When  $q \neq 0$ , the function has a constant term whose value is

$$\frac{1}{4}q - \frac{5}{192}q^3 + \frac{1363}{2\ 21184}q^5 + O(q^7). \quad (5)$$

The graph of  $ce_2(z, 2)$  is shown in Fig. 3. This function is periodic in  $z$  with period  $\pi$ .

In the particular case of  $m = 0$  in (1), (2), we obtain

$$\begin{aligned} ce_0(z, q) = & 1 - \frac{1}{2}q \cos 2z + \frac{1}{32}q^2 \cos 4z - \frac{1}{128}q^3 \left( \frac{1}{9} \cos 6z - 7 \cos 2z \right) + \\ & + \frac{1}{73728}q^4 (\cos 8z - 320 \cos 4z) + O(q^5), \end{aligned} \quad (6)$$

with 
$$a = -\frac{1}{2}q^2 + \frac{7}{128}q^4 - \frac{29}{2304}q^6 + O(q^8). \quad (7)$$

Then  $a = 0$  and  $ce_0 = 1$  for  $q = 0$ . Here again the function has a constant term. In general this holds for all the functions  $ce_{2n}$ , but not for  $ce_{2n+1}$ .

To derive the sine type function of order  $m$ , replace  $\cos mz$  in (1) by  $\sin mz$  and  $c_r(z)$  by  $s_r(z)$ . The solution obtained is either  $se_{2n+1}$  or

$se_{2n+2}$ ,† according as  $m$  is odd or even. If  $m = 2$ , we have

$$\begin{aligned} se_2(z, q) = & \sin 2z - \frac{1}{12}q \sin 4z + \frac{1}{384}q^2 \sin 6z - \\ & - \frac{1}{512}q^3 \left( \frac{1}{45} \sin 8z - \frac{5}{27} \sin 4z \right) + \\ & + \frac{1}{4096}q^4 \left( \frac{1}{540} \sin 10z - \frac{37}{540} \sin 6z \right) + O(q^5), \quad (8) \end{aligned}$$

$$\text{with} \quad a = 4 - \frac{1}{12}q^2 + \frac{5}{13824}q^4 + O(q^6). \quad (9)$$

FIG. 3.

FIG. 4.

FIG. 3. Graphs of  $ce_0(z, 2)$ ,  $ce_0(z, 8)$ ,  $ce_2(z, 2)$ ,  $ce_4(z, 2)$  over a period  $\pi$ . For  $q$  finite  $\neq 0$ ,  $ce_0 > 0$ . As  $q \rightarrow +\infty$ ,  $ce_0(m\pi, q) \rightarrow 0$ .

FIG. 4. Graphs of  $se_2(z, 2)$ ,  $se_4(z, 2)$ ,  $se_6(z, 2)$  over a period  $\pi$ .

When  $q = 0$ ,  $a$  reduces to 4 and  $se_2(z, 0) = \sin 2z$ . The function  $se_2(z, q)$  is periodic in  $z$  with period  $\pi$ . This is shown graphically in Fig. 4.

**2.151. Formulae for  $a$ .** We designate the characteristic numbers for  $ce_m(z, q)$  and  $se_m(z, q)$  by  $a_m$ ,  $b_m$  respectively. Then

$$a_0 = -\frac{1}{2}q^2 + \frac{7}{128}q^4 - \frac{29}{2304}q^6 + \frac{68687}{18874368}q^8 + O(q^{10}). \quad (1)$$

$$\begin{aligned} b_1 = & 1 - q - \frac{1}{8}q^2 + \frac{1}{64}q^3 - \frac{1}{1536}q^4 - \frac{11}{36864}q^5 + \\ & + \frac{49}{589824}q^6 - \frac{55}{9437184}q^7 - \frac{265}{113246208}q^8 + O(q^9). \quad (2) \end{aligned}$$

$$a_1 = \text{write } -q \text{ for } q \text{ in (2)}. \quad (3)$$

† The significance of  $2n+2$  in place of  $2n$  is that  $n$  represents the number of real zeros of  $ce_{2n}$ ,  $ce_{2n+1}$ ,  $se_{2n+1}$ ,  $se_{2n+2}$  in the open interval  $0 < z < \frac{1}{2}\pi$  (see Chap. XII).

$$b_2 = 4 - \frac{1}{12}q^2 + \frac{5}{13824}q^4 - \frac{289}{796\ 26240}q^6 + \frac{21391}{45\ 86471\ 42400}q^8 + O(q^{10}). \quad (4)$$

$$a_2 = 4 + \frac{5}{12}q^2 - \frac{763}{13824}q^4 + \frac{10\ 02401}{796\ 26240}q^6 - \frac{16690\ 68401}{45\ 86471\ 42400}q^8 + O(q^{10}). \quad (5)$$

$$b_3 = 9 + \frac{1}{16}q^2 - \frac{1}{64}q^3 + \frac{13}{20480}q^4 + \frac{5}{16384}q^5 - \frac{1961}{235\ 92960}q^6 + \\ + \frac{609}{1048\ 57600}q^7 + O(q^8). \quad (6)$$

$$a_3 = \text{write } -q \text{ for } q \text{ in (6)}. \quad (7)$$

$$b_4 = 16 + \frac{1}{30}q^2 - \frac{317}{8\ 64000}q^4 + \frac{10049}{27216\ 00000}q^6 + O(q^8). \quad (8)$$

$$a_4 = 16 + \frac{1}{30}q^2 + \frac{433}{8\ 64000}q^4 - \frac{5701}{27216\ 00000}q^6 + O(q^8). \quad (9)$$

$$b_5 = 25 + \frac{1}{48}q^2 + \frac{11}{7\ 74144}q^4 - \frac{1}{1\ 47456}q^5 + \frac{37}{8918\ 13888}q^6 + O(q^7). \quad (10)$$

$$a_5 = \text{write } -q \text{ for } q \text{ in (10)}. \quad (11)$$

$$b_6 = 36 + \frac{1}{70}q^2 + \frac{187}{439\ 04000}q^4 - \frac{58\ 61633}{9293\ 59872\ 00000}q^6 + O(q^8). \quad (12)$$

$$a_6 = 36 + \frac{1}{70}q^2 + \frac{187}{439\ 04000}q^4 + \frac{67\ 43617}{9293\ 59872\ 00000}q^6 + O(q^8). \quad (13)$$

When  $m \geq 7$ , the following formula is correct as far as and including the term in  $q^6$ :

$$a_m, b_m = m^2 + \frac{1}{2(m^2-1)}q^2 + \frac{5m^2+7}{32(m^2-1)^3(m^2-4)}q^4 + \\ + \frac{9m^4+58m^2+29}{64(m^2-1)^5(m^2-4)(m^2-9)}q^6 + \dots \quad (14)$$

These formulae may be used to calculate  $a$  when  $q$  is small enough and of either sign. For equal accuracy,  $q$  may increase with increase in  $m$ . It must not be inferred from (14) that when  $m \geq 7$ ,  $a_m = b_m$ . Series (12), (13) for  $b_6$ ,  $a_6$  are identical up to  $O(q^4)$ , but *not* thereafter.† An extension of (14) to higher orders of  $q$  would show the same behaviour. As  $|q| \rightarrow 0$ ,  $a_m \rightarrow b_m$ , but for  $|q| > 0$ ,  $(a_m - b_m) \neq 0$ ,

† For  $m \geq 3$ , the series for  $a_m$ ,  $b_m$  are identical up to  $q^{m-1}$  or  $q^{m-2}$  according as  $m$  is odd or even.

although it is very small near  $q = 0$ . Under this condition the characteristic curves for  $ce_m$ ,  $se_m$  are substantially coincident (see Fig. 8). In (14) when  $m^2$  is much greater than any subsequent term,  $a_m$ ,  $b_m$  are almost constant, so the characteristic curves are practically parallel to the  $q$ -axis.

### 2.152. Remarks on the periodic Mathieu functions of integral order.

1. The functions  $ce_{2n}$ ,  $n = 0, 1, 2, \dots$ , have period  $\pi$ . There is a constant term in the series, which is a function of  $q$ . As a consequence,  $ce_0$  is never negative, although oscillatory.
2. The functions  $ce_{2n+1}$ ,  $n = 0, 1, 2, \dots$ , have period  $2\pi$ . There is no constant term in the series.
3. The functions  $se_{2n+1}$ ,  $n = 0, 1, 2, \dots$ , have period  $2\pi$ . There is no constant term in the series.
4. The functions  $se_{2n+2}$ ,  $n = 0, 1, 2, \dots$ , have period  $\pi$ . There is no constant term in the series.
5. All the above functions have  $n$  real zeros in  $0 < z < \frac{1}{2}\pi$ .

**2.153. Dynamical illustration.** The differential equation may be written

$$\frac{d^2y}{dt^2} + ay = (2q \cos 2t)y. \quad (1)$$

Referring to Fig. 5 (A), if  $a = s/m$ ,  $2q = f_0/m$ , (1) becomes

$$my'' + sy = (f_0 \cos 2t)y, \quad (2)$$

which is the differential equation of the mechanism illustrated there, provided  $y/l \ll 1$ ,  $\omega = 1$ . A mass  $m$  is fixed to a massless helical spring of stiffness  $s$ , and driven along the linear axis of the spring by a force  $(f_0 \cos 2t)y$ , which depends upon the displacement  $y$ . If  $m$ ,  $s$ ,  $f_0$  have the appropriate values,  $y$  may take any of the forms  $ce_{2n}$ ,  $ce_{2n+1}$ ,  $se_{2n+1}$ ,  $se_{2n+2}$ . Suppose  $y = ce_1(t, q)$ , then the motion is described by (16) § 2.13, and the component  $\cos t$  is a *sub-harmonic* of  $\cos 2t$  in (2) above. This remark applies also if  $m$ ,  $s$ ,  $f_0$  are such that  $y = se_1(t, q)$ , by virtue of the component  $\sin t$  in (2) § 2.14. Hence in any system (dynamical, electrical, etc.) represented by (2), if the parameters  $a$ ,  $q$  have certain interrelated values, there will be a sub-harmonic of  $f_0 \cos 2t$ . In any event, so long as the parameters are those for a function having period  $\pi$ ,  $2\pi$ , the displacement (or its equivalent) has an infinite number of harmonic components corre-

sponding to the various terms in the series, e.g. (16) § 2.13, (2) § 2.14, (3) § 2.150. Additional comment is made in §§ 15.40, 15.41.

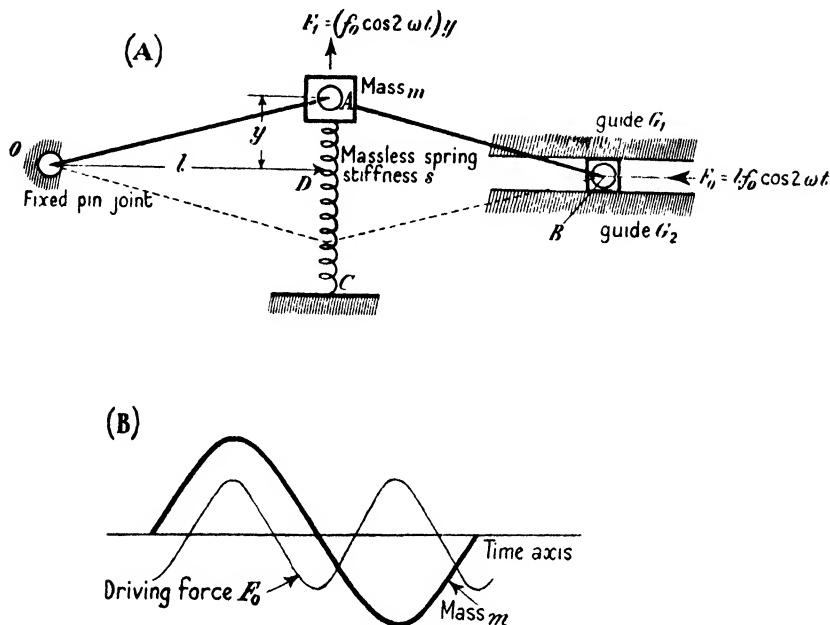

FIG. 5. (A) Schematic diagram (plan) of mechanism illustrating Mathieu's equation. (B) Curves illustrating motion of  $m$  and the point  $B$  when a sub-harmonic of pulsance  $\omega$  occurs.

**2.16. Mathieu functions of fractional order.**† We define a function of order  $\nu$  (real but either rational or irrational and positive), to be one which satisfies Mathieu's equation and reduces to  $\cos \nu z$ ,  $\sin \nu z$  when  $q = 0$ . The normalization in this section corresponds to that of § 2.11, so the coefficient of  $\cos \nu z$ ,  $\sin \nu z$  is unity for *all*  $q$ . If we assume that

$$\text{ce}_\nu(z, q) = \cos \nu z + \sum_{r=1}^{\infty} q^r c_r(z), \quad (1)$$

$$\text{se}_\nu(z, q) = \sin \nu z + \sum_{r=1}^{\infty} q^r s_r(z), \quad (2)$$

$$a = \nu^2 + \sum_{r=1}^{\infty} \alpha_r q^r, \quad (3)$$

† Although the title of this chapter implies functions of integral order only, those of fractional order are introduced here because their expansions *under the normalization* of § 2.11 are obtained in ascending powers of  $q$  by a procedure akin to that used for the former. A different definition is given in § 4.71 under the normalization of § 2.21.

and proceed analytically as in §2.13, the following results are obtained:

$$\begin{aligned} \text{ce}_\nu(z, q) = & \cos \nu z - \frac{1}{4}q \left[ \frac{\cos(\nu+2)z}{(\nu+1)} - \frac{\cos(\nu-2)z}{(\nu-1)} \right] + \\ & + \frac{1}{32}q^2 \left[ \frac{\cos(\nu+4)z}{(\nu+1)(\nu+2)} + \frac{\cos(\nu-4)z}{(\nu-1)(\nu-2)} \right] - \\ & - \frac{1}{128}q^3 \left[ \frac{(\nu^2+4\nu+7)\cos(\nu+2)z}{(\nu-1)(\nu+1)^3(\nu+2)} - \frac{(\nu^2-4\nu+7)\cos(\nu-2)z}{(\nu+1)(\nu-1)^3(\nu-2)} \right] + \\ & + \frac{\cos(\nu+6)z}{3(\nu+1)(\nu+2)(\nu+3)} - \frac{\cos(\nu-6)z}{3(\nu-1)(\nu-2)(\nu-3)} \Big] + \dots, \quad (4) \end{aligned}$$

$$\begin{aligned} \text{se}_\nu(z, q) = & \sin \nu z - \frac{1}{4}q \left[ \frac{\sin(\nu+2)z}{(\nu+1)} - \frac{\sin(\nu-2)z}{(\nu-1)} \right] + \\ & + \frac{1}{32}q^2 \left[ \frac{\sin(\nu+4)z}{(\nu+1)(\nu+2)} + \frac{\sin(\nu-4)z}{(\nu-1)(\nu-2)} \right] - \dots, \quad (5) \end{aligned}$$

$$\begin{aligned} a = & \nu^2 + \frac{1}{2(\nu^2-1)}q^2 + \frac{(5\nu^2+7)}{32(\nu^2-1)^3(\nu^2-4)}q^4 + \\ & + \frac{9\nu^4+58\nu^2+29}{64(\nu^2-1)^5(\nu^2-4)(\nu^2-9)}q^6 + \dots \quad (6) \end{aligned}$$

These formulae are suitable for computation when  $q^2/2(\nu^2-1) \ll \nu^2$ ,  $\nu > 0$ .  $a$  has the same value for both solutions for any  $q$ , so (4), (5) coexist, and are linearly independent. Thus the complete solution with two arbitrary constants is

$$y = A \text{ce}_\nu(z, q) + B \text{se}_\nu(z, q), \quad (7)$$

provided  $\nu$  is non-integral. (4), (5) constitute a fundamental system.

Since (6) is even in  $q$ , the characteristic curves, showing the relationship between  $a$ ,  $q$ , for  $\text{ce}_\nu(z, q)$ ,  $\text{se}_\nu(z, q)$  are symmetrical about the  $a$ -axis. Put  $\nu = (m+\beta)$ ,  $m$  being a positive integer, and  $0 < \beta < 1$ . If  $\beta = p/s$ , a rational fraction in its lowest terms, the functions have period  $2\pi s$  in  $z$ ,  $s \geq 2$ . If  $\beta$  is irrational, the functions are non-periodic, but they are bounded and tend neither to zero nor infinity as  $z \rightarrow +\infty$ .

**2.17. Preferred form of series for  $\text{ce}_m(z, q)$ ,  $\text{se}_m(z, q)$ .** The form of the series given hitherto precludes the application of standard convergence tests. In [180] it is shown that by constructing a 'fonction majorante', the series for  $\text{ce}_0(z, q)$  converges if  $|4q|^2 < 1$ . This is the only case which has been treated. Generally the series *appear*

to converge if  $q$  is small, but diverge when it is large enough. The preferred form of the series is given below [52, 88, 95, 162, 196] for  $q$  positive:

$$\text{ce}_{2n}(z, q) = \sum_{r=0}^{\infty} A_{2r}^{(2n)} \cos 2rz \quad \begin{array}{l} \text{Characteristic} \\ \text{number} \end{array} \quad (a_{2n}) \quad (1)$$

$$\text{ce}_{2n+1}(z, q) = \sum_{r=0}^{\infty} A_{2r+1}^{(2n+1)} \cos(2r+1)z \quad (a_{2n+1}) \quad (2)$$

$$\text{se}_{2n+1}(z, q) = \sum_{r=0}^{\infty} B_{2r+1}^{(2n+1)} \sin(2r+1)z \quad (b_{2n+1}) \quad (3)$$

$$\text{se}_{2n+2}(z, q) = \sum_{r=0}^{\infty} B_{2r+2}^{(2n+2)} \sin(2r+2)z \quad (b_{2n+2}) \quad (4)$$

In these series  $A$ ,  $B$  are functions of  $q$ . This will be evident if we express (16) § 2.13 in the form (2), with  $n = 0$ . Then

$$\text{ce}_1(z, q) = A_1 \cos z + A_3 \cos 3z + A_5 \cos 5z + \dots, \quad (5)$$

where under the convention of § 2.11

$$A_1 = 1 \text{ for all } q; \quad A_3 = -\frac{1}{8}q \left( 1 + \frac{1}{8}q + \frac{1}{192}q^2 - \frac{11}{4608}q^3 + \dots \right);$$

$$A_5 = \frac{1}{192}q^2 \left( 1 + \frac{1}{6}q + \frac{1}{128}q^2 + \dots \right), \quad \text{and so on.}$$

When the  $A$ ,  $B$  are obtained by the method used in § 3.13, and the solutions are normalized in accordance with § 2.21, their convergence is readily demonstrated. This is left until § 3.21.

**2.18. Changing the sign of  $q$ .** If in (1) § 2.10 we write  $\pm(\frac{1}{2}\pi \pm z)$  for  $z$ , it becomes

$$y'' + (a + 2q \cos 2z)y = 0. \quad (1)$$

Consequently the solutions of (1) § 2.10 with period  $\pi$ ,  $2\pi$ ,  $q$  being negative, are obtained if the above substitution is made in (1)–(4) § 2.17. Hence, standardizing on  $(\frac{1}{2}\pi - z)$ , we get [52, 95]:

$$\begin{aligned} \text{ce}_{2n}(z, -q) &= (-1)^n \text{ce}_{2n}(\tfrac{1}{2}\pi - z, q) \\ &= (-1)^n \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} \cos 2rz \quad (a_{2n}), \end{aligned} \quad (2)$$

$$\begin{aligned} \text{ce}_{2n+1}(z, -q) &= (-1)^n \text{se}_{2n+1}(\tfrac{1}{2}\pi - z, q) \\ &= (-1)^n \sum_{r=0}^{\infty} (-1)^r B_{2r+1}^{(2n+1)} \cos(2r+1)z \quad (b_{2n+1}), \end{aligned} \quad (3)$$

$$\begin{aligned} \text{se}_{2n+1}(z, -q) &= (-1)^n \text{ce}_{2n+1}(\tfrac{1}{2}\pi - z, q) \\ &= (-1)^n \sum_{r=0}^{\infty} (-1)^r A_{2r+1}^{(2n+1)} \sin(2r+1)z \quad (a_{2n+1}), \quad (4) \end{aligned}$$

$$\begin{aligned} \text{se}_{2n+2}(z, -q) &= (-1)^n \text{se}_{2n+2}(\tfrac{1}{2}\pi - z, q) \\ &= (-1)^n \sum_{r=0}^{\infty} (-1)^r B_{2r+2}^{(2n+2)} \sin(2r+2)z \quad (b_{2n+2}). \quad (5) \end{aligned}$$

Since  $\text{ce}_{2n+1}(z, -q)$ ,  $\text{se}_{2n+1}(z, -q)$  entail cosine and sine series, respectively, they are derived from  $\text{se}_{2n+1}(z, q)$  and  $\text{ce}_{2n+1}(z, q)$ . Accordingly the  $A$ ,  $B$ , and the characteristic numbers are interchanged, i.e.  $(A, a)$  and  $(B, b)$  accompany each other. The multiplier  $(-1)^n$  ensures that when  $q = 0$ , the functions reduce to  $+\cos mz$  or  $+\sin mz$  as the case may be.

Any linear differential equation of the second order has two linearly independent solutions, that is to say, they are not proportional. All solutions of integral order obtained hitherto are of the first kind. The second solutions require separate consideration, and being of less practical importance than the first kind, are treated in Chapter VII.

**2.19. Orthogonality of the periodic functions  $\text{ce}_m$ ,  $\text{se}_m$ .** Let  $y_1, y_2$  be solutions of

$$y'' + (a - 2q \cos 2z)y = 0, \quad (1)$$

for the same value of  $q$ , but usually different values of  $a$ , e.g.  $a_1, a_2$ . Then

$$y_1'' + (a_1 - 2q \cos 2z)y_1 = 0 \quad \text{and} \quad y_2'' + (a_2 - 2q \cos 2z)y_2 = 0. \quad (2)$$

Multiplying the first of these equations by  $y_2$ , the second by  $y_1$ , and subtracting, gives

$$y_1'' y_2 - y_2'' y_1 = (a_2 - a_1)y_1 y_2. \quad (3)$$

Integrating both sides of (3) between the limits  $z_1, z_2$ , we get

$$\int_{z_1}^{z_2} y_2 dy_1' - \int_{z_1}^{z_2} y_1 dy_2' = (a_2 - a_1) \int_{z_1}^{z_2} y_1 y_2 dz, \quad (4)$$

which after integration by parts becomes

$$[y_1' y_2 - y_2' y_1]_{z_1}^{z_2} = (a_2 - a_1) \int_{z_1}^{z_2} y_1 y_2 dz. \quad (5)$$

For a given  $q$ , the  $a$  corresponding to  $y_1 = \text{ce}_m(z, q)$ ,  $y_2 = \text{ce}_p(z, q)$ ,

$m \neq p$ , are different. These functions have period  $\pi$  or  $2\pi$ , so with  $z_1 = 0$ ,  $z_2 = 2\pi$ , the l.h.s. of (5) vanishes. Hence, if  $m \neq p$ ,

$$\int_0^{2\pi} \text{ce}_m(z, q) \text{ce}_p(z, q) dz = 0. \quad (6)$$

When  $m = 2n$ , an even integer, from (1) § 2.17, we have

$$\int_0^{2\pi} \text{ce}_{2n}^2(z, q) dz = \int_0^{2\pi} \sum_{r=0}^{\infty} [A_{2r}^{(2n)} \cos 2rz]^2 dz = \sum_{r=0}^{\infty} \int_0^{2\pi} [A_{2r}^{(2n)}]^2 \cos^2 2rz dz, \quad (7)$$

since by § 3.21 the series concerned are absolutely and uniformly convergent, term-by-term integration being permissible. The other integrals vanish by virtue of orthogonality of the circular functions. Thus

$$\int_0^{2\pi} \text{ce}_{2n}^2(z, q) dz = 2\pi[A_0^{(2n)}]^2 + \pi \sum_{r=1}^{\infty} [A_{2r}^{(2n)}]^2. \quad (8)$$

The results given below may be established in a similar manner:

$$\int_0^{2\pi} \text{ce}_{2n+1}^2(z, q) dz = \pi \sum_{r=0}^{\infty} [A_{2r+1}^{(2n+1)}]^2. \quad (9)$$

$$\int_0^{2\pi} \text{se}_m(z, q) \text{se}_p(z, q) dz = 0 \quad (m \neq p). \quad (10)$$

$$\int_0^{2\pi} \text{se}_{2n+1}^2(z, q) dz = \pi \sum_{r=0}^{\infty} [B_{2r+1}^{(2n+1)}]^2. \quad (11)$$

$$\int_0^{2\pi} \text{ce}_m(z, q) \text{se}_p(z, q) dz = 0, \quad m, p, \text{ positive integers.} \quad (12)$$

$$\int_0^{2\pi} \text{se}_{2n+2}^2(z, q) dz = \pi \sum_{r=0}^{\infty} [B_{2r+2}^{(2n+2)}]^2. \quad (13)$$

These results are valid for all values of  $q$ , and lead us to the important conclusion that  $\text{ce}_m(z, q)$ ,  $\text{se}_m(z, q)$  are orthogonal. This fundamental property is used in §§ 4.90, 10.60.

**2.191. A fundamental identity.** In (5) § 2.19 let  $y_1, y_2$  be independent solutions of (1) § 2.19 for the same  $a, q$ . Then with  $z_1 = 0, z_2 = z$ , we get the Wronskian

$$y_1(z)y_2'(z) - y_2(z)y_1'(z) = y_1(0)y_2'(0) - y_2(0)y_1'(0) = c^2, \quad \text{a constant.} \quad (1)$$

If  $y_1(0) = y_2'(0) = 1$ , and  $y_2(0) = y_1'(0) = 0$ ,  $c^2 = 1$  and we obtain

$$y_1(z)y_2'(z) - y_2(z)y_1'(z) \equiv 1. \quad (2)$$

For a given pair of independent solutions,  $c^2$  will in general vary with  $q$ .

## 2.20. Orthogonality of functions of rational fractional order.

Since  $y_1, y_2$  in (5) § 2.19 are *any* solutions for the same  $q$ , the formula is valid for functions of rational fractional order  $\nu$ . Then by § 2.16 the period is  $2\pi s$ , so with  $z_1 = 0$ ,  $z_2 = 2\pi s$  in (5) § 2.19, we have

$$\begin{aligned} \int_0^{2\pi s} \text{ce}_\nu(z, q) \text{ce}_\mu(z, q) dz &= \int_0^{2\pi s} \text{se}_\nu(z, q) \text{se}_\mu(z, q) dz \\ &= \int_0^{2\pi s} \text{ce}_\nu(z, q) \text{se}_\mu(z, q) dz = 0, \end{aligned} \quad (1)$$

provided  $\nu \neq \mu$  in the first two integrals. Also

$$\int_0^{2\pi s} \text{ce}_\nu^2(z, q) dz \neq 0, \quad \int_0^{2\pi s} \text{se}_\nu^2(z, q) dz \neq 0. \quad (2)$$

Hence the *periodic* functions of (rational) fractional order are orthogonal. The value of these integrals is given in § 4.72.

**2.21. Normalization of  $\text{ce}_m(z, q)$ ,  $\text{se}_m(z, q)$ .** In § 2.11 we introduced a convention that the coefficients of  $\cos mz$ ,  $\sin mz$  should be unity for *all* values of  $q$ . Thus in (1)–(4) § 2.17 we should then have  $A_m^{(m)} = B_m^{(m)} = 1$  for all  $q$ . It will be shown later that constancy of these coefficients leads to undesirable consequences. Accordingly we now introduce an improved convention based upon § 2.19 [52, 95]. We shall make definite or *normalize* the functions  $\text{ce}_m(z, q)$ ,  $\text{se}_m(z, q)$  by the stipulation that

$$\frac{1}{\pi} \int_0^{2\pi} \text{ce}_m^2(z, q) dz = \frac{1}{\pi} \int_0^{2\pi} \text{se}_m^2(z, q) dz = 1, \quad (1)$$

for all real values of  $q$ . Then by (1) above and (8) § 2.19, we have

$$2[A_0^{(2n)}]^2 + \sum_{r=1}^{\infty} [A_{2r}^{(2n)}]^2 = 1. \quad (2)$$

Now  $\text{ce}_0(z, 0) = 1$  by our convention of § 2.11, so to normalize in

accordance with (1) above, its constant term must be  $A_0^{(0)} = 2^{-1}$  for  $q = 0$ , since

$$\frac{1}{\pi} \int_0^{2\pi} dz = 2. \quad (3)$$

For  $\text{ce}_{2n+1}$ ,  $\text{se}_{2n+1}$ ,  $\text{se}_{2n+2}$  we have, respectively, [52]

$$1 = \sum_{r=0}^{\infty} [A_{2r+1}^{(2n+1)}]^2 = \sum_{r=0}^{\infty} [B_{2r+1}^{(2n+1)}]^2 = \sum_{r=0}^{\infty} [B_{2r+2}^{(2n+2)}]^2. \quad (4)$$

The normalization (1) entails a mean square value of  $1/2$  over the interval  $(0, 2\pi)$ , which is the same as that for the circular functions. It is convenient in applications when the orthogonal properties of the Mathieu functions are used.

The functions of fractional order may be normalized in like manner, but this is postponed till § 4.72.

**2.22. Relationships.** The following are easily established from what precedes:

$$\begin{matrix} \text{ce}_m(n\pi+z) = & \text{ce}_m(n\pi-z), \\ \text{se}_m & -\text{se}_m \end{matrix} \quad (1)$$

$$\begin{matrix} \text{ce}_m(\frac{1}{2}\pi+z) = (-1)^m \text{ce}_m(\frac{1}{2}\pi-z), \\ \text{se}_{m+1} & \text{se}_{m+1} \end{matrix} \quad (2)$$

$$\begin{matrix} \text{ce}_m(\pi+z) = (-1)^m \text{ce}_m(z), \\ \text{se}_m & \text{se}_m \end{matrix} \quad (3)$$

From these relationships it is seen to be sufficient to give tabular values of the ordinary Mathieu functions in the interval  $0 \leq z \leq \frac{1}{2}\pi$  for  $q > 0$ . When  $q < 0$ , the appropriate values may be derived from the foregoing by aid of (2)–(5) § 2.18.

$$\text{Also} \quad \text{ce}_{2n+1}(r+\frac{1}{2})\pi = \text{se}_{2n+1}(r\pi) = \text{se}_{2n+2}(\frac{1}{2}r\pi) = 0. \quad (4)$$

When  $z \rightarrow \frac{1}{2}\pi$

$$\begin{aligned} &(-1)^n \text{ce}_{2n}(z, q), \quad (-1)^n \text{ce}_{2n+1}(z, q)/\cos z, \\ &(-1)^n \text{se}_{2n+1}(z, q), \quad (-1)^n \text{se}_{2n+2}(z, q)/\cos z, \end{aligned} \quad (5)$$

are positive.

**2.23. Transformation of  $y'' + (a - 2q \cos 2z)y = 0$ .**

1°. Substitute  $x = u(z)$ , a continuous function of  $z$ , and we get

$$\left(\frac{du}{dz}\right)^2 \frac{d^2y}{du^2} + \frac{d^2u}{dz^2} \frac{dy}{du} + (a - 2q \cos 2z)y = 0. \quad (1)$$

If  $u = 2k \cos z$ ,  $q = k^2$ , (1) gives the transformed version of Mathieu's equation as

$$(u^2 - 4k^2) \frac{d^2 y}{du^2} + u \frac{dy}{du} + (u^2 - a - 2k^2)y = 0. \quad (2)$$

2°. Let  $y = u(z)f(z)$ ,  $u, f$  being continuous functions of  $z$ , then we obtain

$$u'' + 2(f'/f)u' + [a + (f''/f) - 2q \cos 2z]u = 0. \quad (3)$$

Take  $f(z) = e^{\kappa z}$ , then  $f'/f = \kappa$ ,  $f''/f = \kappa^2$ , so (3) becomes

$$u'' + 2\kappa u' + [(a + \kappa^2) - 2q \cos 2z]u = 0. \quad (4)$$

The solution of (4) is  $u = ye^{-\kappa z}$ , where  $y$  is a solution of Mathieu's equation.

**2.30. Modified Mathieu functions of the first kind of integral order,  $q$  positive.** If in (1) § 2.10 we write  $iz$  for  $z$ , the equation becomes

$$\frac{d^2 y}{dz^2} - (a - 2q \cosh 2z)y = 0. \quad (1)$$

This is the canonical form of the second equation found by Mathieu in his analysis of the elliptical membrane. For the values of  $a$  corresponding to  $ce_m(z, q)$ ,  $se_m(z, q)$  the first solutions of (1) are derived by substituting  $iz$  for  $z$  in (1)–(4) § 2.17. Thus we have

$$Ce_{2n}(z, q) = ce_{2n}(iz, q) = \sum_{r=0}^{\infty} A_{2r}^{(2n)} \cosh 2rz \quad (a_{2n}), \quad (2)$$

$$Ce_{2n+1}(z, q) = ce_{2n+1}(iz, q) = \sum_{r=0}^{\infty} A_{2r+1}^{(2n+1)} \cosh(2r+1)z \quad (a_{2n+1}), \quad (3)$$

$$Se_{2n+1}(z, q) = -i se_{2n+1}(iz, q) = \sum_{r=0}^{\infty} B_{2r+1}^{(2n+1)} \sinh(2r+1)z \quad (b_{2n+1}), \quad (4)$$

$$Se_{2n+2}(z, q) = -i se_{2n+2}(iz, q) = \sum_{r=0}^{\infty} B_{2r+2}^{(2n+2)} \sinh(2r+2)z \quad (b_{2n+2}). \quad (5)$$

These are defined to be modified Mathieu functions of the first kind of integral order† for  $q > 0$ . (2), (5) are periodic in  $z$ , with period  $\pi i$ , whilst (3), (4) are also periodic with period  $2\pi i$ .

**2.31. Changing the sign of  $q$ .** Equation (1) § 2.30 then becomes

$$\frac{d^2 y}{dz^2} - (a + 2q \cosh 2z)y = 0. \quad (1)$$

This is obtained if  $z$  in (1) § 2.18 is replaced by  $iz$ , or if  $(\frac{1}{2}\pi i + z)$  is

† The use of capital letters to denote the modified Mathieu functions is due to H. Jeffreys [104, p. 459].

written for  $z$  in (1) § 2.30. Changing the arguments in either (2)–(5) § 2.18 or in (2)–(5) § 2.30 leads to the following solutions of (1):

$$\begin{aligned} \text{Ce}_{2n}(z, -q) &= \text{ce}_{2n}(iz, -q) \\ &= (-1)^n \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} \cosh 2rz \quad (a_{2n}), \end{aligned} \quad (2)$$

$$\begin{aligned} \text{Ce}_{2n+1}(z, -q) &= \text{ce}_{2n+1}(iz, -q) \\ &= (-1)^n \sum_{r=0}^{\infty} (-1)^r B_{2r+1}^{(2n+1)} \cosh(2r+1)z \quad (b_{2n+1}), \end{aligned} \quad (3)$$

$$\begin{aligned} \text{Se}_{2n+1}(z, -q) &= -i \text{se}_{2n+1}(iz, -q) \\ &= (-1)^n \sum_{r=0}^{\infty} (-1)^r A_{2r+1}^{(2n+1)} \sinh(2r+1)z \quad (a_{2n+1}), \end{aligned} \quad (4)$$

$$\begin{aligned} \text{Se}_{2n+2}(z, -q) &= -i \text{se}_{2n+2}(iz, -q) \\ &= (-1)^n \sum_{r=0}^{\infty} (-1)^r B_{2r+2}^{(2n+2)} \sinh(2r+2)z \quad (b_{2n+2}). \end{aligned} \quad (5)$$

(2), (5) have period  $\pi i$ , while (3), (4) have period  $2\pi i$  in  $z$ . The interchange of the coefficients  $A$ ,  $B$ , and characteristic numbers  $a_{2n+1}$ ,  $b_{2n+1}$ , in (3), (4) §§ 2.30, 2.31, should be observed—see remarks in § 2.18. The multiplier  $(-1)^n$  ensures that when  $q = 0$ , the functions reduce to  $+\cosh mz$ , or  $+\sinh mz$ , as the case may be. (2)–(5) may be regarded as modified Mathieu functions of the first kind for  $q$  negative.

### III

#### CALCULATION OF CHARACTERISTIC NUMBERS AND COEFFICIENTS

**3.10. Recurrence relations for the coefficients.** If each series (1)–(4) § 2.17 is substituted in turn in  $y'' + (a - 2q \cos 2z)y = 0$ , and the coefficients of  $\cos 2rz$ ,  $\cos(2r+1)z$ ,  $\sin(2r+1)z$ ,  $\sin(2r+2)z$  equated to zero for  $r = 0, 1, 2, \dots$ , the following recurrence relations are obtained [52, 88]:

$$\left. \begin{aligned} aA_0 - qA_2 &= 0 \\ (a-4)A_2 - q(A_4 + 2A_0) &= 0 \\ (a-4r^2)A_{2r} - q(A_{2r+2} + A_{2r-2}) &= 0 \end{aligned} \right\} \begin{array}{l} \text{for } ce_{2n}(z, q), \\ \\ r \geq 2. \end{array} \quad (1)$$

$$\left. \begin{aligned} (a-1-q)A_1 - qA_3 &= 0 \\ [a-(2r+1)^2]A_{2r+1} - q(A_{2r+3} + A_{2r-1}) &= 0 \end{aligned} \right\} \begin{array}{l} \text{for } ce_{2n+1}(z, q), \\ \\ r \geq 1. \end{array} \quad (2)$$

$$\left. \begin{aligned} (a-1+q)B_1 - qB_3 &= 0 \\ [a-(2r+1)^2]B_{2r+1} - q(B_{2r+3} + B_{2r-1}) &= 0 \end{aligned} \right\} \begin{array}{l} \text{for } se_{2n+1}(z, q), \\ \\ r \geq 1. \end{array} \quad (3)$$

$$\left. \begin{aligned} (a-4)B_2 - qB_4 &= 0 \\ (a-4r^2)B_{2r} - q(B_{2r+2} + B_{2r-2}) &= 0 \end{aligned} \right\} \begin{array}{l} \text{for } se_{2n+2}(z, q), \\ \\ r \geq 2. \end{array} \quad (4)$$

For simplicity the superscripts  $2n$ ,  $2n+1$ ,  $2n+2$  have been omitted from the  $A$  and  $B$ . The respective recurrence relations for  $ce_{2n}(z, -q)$ , etc.,  $Ce_{2n}(z, q), \dots$ ,  $Ce_{2n}(z, -q), \dots$  are identical with those above.† To ensure convergence of the series in §§ 2.17, 2.30 it is necessary that  $A_m \rightarrow 0$ ,  $B_m \rightarrow 0$  as  $m \rightarrow +\infty$ .

**3.11. Calculation of  $a$  and the  $A$ ,  $B$ .** If  $q$  is small enough, the formulae for  $a$  given in § 2.151 may be used. In general, however,  $a$  must be calculated using one of the methods illustrated below. We adopt the normalization of § 2.21, thereby entailing coefficients which differ from those obtained using the normalization of § 2.11 [52, 88].

We commence with the function  $ce_0(z, 8)$ , i.e.  $q = 8$ , which is well outside the range of the formulae in Chapter II. First we derive an infinite continued fraction. From the second formula in (1) § 3.10, we have

$$(4-a)A_2 + q(A_4 + 2A_0) = 0. \quad (1)$$

† Note the factor 2 for  $A_0$ .

‡ Using  $q$  or  $-q$  as the case may be.

Writing  $v_0 = A_2/A_0, v_2 = A_4/A_2$ , then  $v_0 v_2 = A_4/A_0$ . Dividing (1) by  $A_0$  and making these substitutions, gives

$$(4-a)v_0 + q(v_0 v_2 + 2) = 0, \quad (2)$$

$$\text{so} \quad -v_0 = \frac{1}{2}q/[1 - \frac{1}{4}(a - qv_2)]. \quad (3)$$

In the same way from the third formula in (1) § 3.10, with

$$v_{2r-2} = A_{2r}/A_{2r-2}, \quad v_{2r} = A_{2r+2}/A_{2r},$$

$$\text{we get} \quad (4r^2 - a)v_{2r-2} + q(v_{2r} v_{2r-2} + 1) = 0,$$

$$\text{so } (r \geq 2) \quad -v_{2r-2} = (q/4r^2)/[1 - (1/4r^2)(a - qv_{2r})], \quad (4)$$

which may be regarded as an alternative form of recurrence relation. Substituting  $r = 2$  in (4) yields

$$-v_2 = (q/16)/[1 - \frac{1}{16}(a - qv_4)], \quad (5)$$

and on inserting this in (3) we get

$$-v_0 = \frac{1}{2}q/[1 - \frac{1}{4}a - (q^2/64)/[1 - \frac{1}{16}(a - qv_4)]]. \quad (6)$$

Putting  $r = 3$  in (4), we obtain a formula for  $v_4$ , which is now substituted in (6). Proceeding thus we ultimately get the infinite continued fraction

$$-v_0 = \frac{\frac{1}{2}q}{1 - \frac{1}{4}a} - \frac{\frac{1}{64}q^2}{1 - \frac{1}{16}a} - \frac{\frac{1}{576}q^2}{1 - \frac{1}{36}a} - \frac{\frac{1}{2304}q^2}{1 - \frac{1}{64}a} - \dots \frac{q^2/16r^2(r-1)^2}{1 - a/4r^2} - \dots \quad (7)$$

From the first formula in (1) § 3.10,  $v_0 = A_2/A_0 = a/q$ , so (7) becomes

$$a = \frac{-\frac{1}{2}q^2}{1 - \frac{1}{4}a} - \frac{\frac{1}{64}q^2}{1 - \frac{1}{16}a} - \frac{\frac{1}{576}q^2}{1 - \frac{1}{36}a} - \frac{\frac{1}{2304}q^2}{1 - \frac{1}{64}a} - \dots, \quad (8)$$

which is in effect a transcendental equation for  $a_{2\pi}$ . Since  $a, q$  are finite, the denominator of the general term approaches unity as  $r \rightarrow +\infty$ , while the numerator tends to zero. Hence (8) is convergent.

**3.12. Computation of  $a_0$  for  $q = 8$ .** We commence by finding an approximate value of  $a_0$  by trial and error. Neglecting all members on the r.h.s. of (8) § 3.11 except the first, we get

$$a_0 = -32/(1 - \frac{1}{4}a_0),$$

$$\text{so} \quad a_0 = 2 \pm (132)^{\frac{1}{2}} \simeq -9.5 \text{ or } +13.5. \quad (1)$$

Substituting  $+13.5$  in the first three members on the r.h.s. of (8) § 3.11 gives the following:

$$\left. \begin{aligned} \frac{1}{576}q^2/(1 - \frac{1}{36}a) &= 0.178, \\ \frac{1}{64}q^2/(1 - \frac{1}{16}a - 0.178) &= -43.6, \\ -\frac{1}{2}q^2/(1 - \frac{1}{4}a + 43.6) &= -0.776. \end{aligned} \right\} \quad (2)$$

The great discrepancy between  $+13.5$  and  $-0.776$  indicates that we chose the wrong root of (1). Suppose we start with  $a_0 = -10$ , then to a first approximation

$$a_0 = -\frac{32}{3.5} - \frac{1}{1.625} - \frac{0.111}{1.278} = -11.2. \quad (3)$$

This is numerically greater than  $-10$ , so we now use the average, namely,  $-10.6$ , and repeat the calculation. Before doing so, we shall obtain an estimate of the number of members from (8) § 3.11 to give a reasonable approximation. The general component is

$$[q^2/16r^2(r-1)^2] / \left\{ 1 - \frac{1}{4r^2}(a - qv_{2r}) \right\}, \quad (4)$$

and as  $r$  increases, we see from (4) § 3.11 that  $v_{2r-2}$  decreases, while in (4) the term  $|qv_{2r}|/4r^2 \ll 1$ , provided  $r$  is large enough. Taking  $r = 6$  in (4) § 3.11, and neglecting  $qv_{2r}/4r^2$ , we get

$$-v_{10} \simeq (1/18)/[1 + (10.6/144)] = 0.052, \quad (5)$$

so  $|qv_{12}|/4r^2 < |qv_{10}|/4 \times 36 \simeq 0.0029$ . We shall presume, that for the purpose of illustrating the method of calculation, the accuracy will be adequate if (8) § 3.11 is terminated at the fifth member on the r.h.s. Thus assuming that  $v_{12}$  may be neglected, we get [88]

$$\begin{aligned} r = 5 & \quad [q^2/16r^2(r-1)^2]/(1 - a/4r^2) \\ & \quad = (1/100)/[1 + (10.6/100)] = 0.00904 \ 0, \\ r = 4 & \quad (1/36)/[1 + (10.6/64) - 0.00904] = 0.02402 \ 0, \\ r = 3 & \quad (1/9)/[1 + (10.6/36) - 0.02402] = 0.08746 \ 0, \\ r = 2 & \quad 1/[1 + (10.6/16) - 0.08746] = 0.63490 \ 4, \\ r = 1 & \quad -32/[1 + (10.6/4) - 0.63490 \ 4] = a_0 = -10.61326 \ 0. \end{aligned} \quad (6)$$

The trial value of  $a_0$  was  $-10.6$ , so (6) differs from this in the fourth significant figure. Taking the average† gives  $a_0 = -10.60663 \ 0$ . If this is used instead of  $-10.6$  and the calculation repeated, the new value of  $a_0$  to six significant figures is  $-10.6067$ . A more accurate result may be obtained by using this value of  $a_0$ , and repeating the computation with  $r = 7$ . To seven decimal places

$$a_0 = -10.60672 \ 92.$$

It is apposite to remark that a formula of the type (7) § 2.15 could

† This procedure is not always expedient.

not be used in the present case where  $q = 8$ . Even for  $q = 0.8$  the accuracy would be low.

**3.13. Computation of coefficients for  $\text{ce}_0(z, 8)$ .** From (5) § 3.12,  $v_{10} \simeq -0.052$ , so using (4) § 3.11, with  $a_0 = -10.6$  to demonstrate the procedure, we obtain

$$r = 5 \quad -v_8 = (2/25)/[1 + (10.6/100) - (2 \times 0.052/25)] \\ \simeq 0.0726 = -A_{10}/A_8, \quad (1)$$

$$r = 4 \quad -v_6 = (2/16)/[1 + (10.6/64) - (2 \times 0.0726/16)] \\ \simeq 0.108 = -A_8/A_6, \quad (2)$$

$$r = 3 \quad -v_4 = (2/9)/[1 + (10.6/36) - (2 \times 0.108/9)] \\ \simeq 0.175 = -A_6/A_4, \quad (3)$$

$$r = 2 \quad -v_2 = (2/4)/[1 + (10.6/16) - (2 \times 0.175/4)] \\ \simeq 0.318 = -A_4/A_2. \quad (4)$$

$$\text{By (3) § 3.11} \quad -v_0 = 4/[1 + (10.6/4) - 2 \times 0.318] \\ \simeq 1.327 = -A_2/A_0. \quad (5)$$

Normalizing the function in accordance with the convention of § 2.21, we have

$$1 = 2A_0^2 + A_2^2 + A_4^2 + A_6^2 + \dots, \quad (6)$$

$$\text{so} \quad 1/A_0^2 = 2 + (A_2/A_0)^2 + (A_4/A_0)^2 + (A_6/A_0)^2 + \dots \quad (7)$$

From (5),  $-A_2 = 1.327A_0$ , so by (4)

$$A_4 = 1.327 \times 0.318A_0 \simeq 0.422A_0. \quad (8)$$

In the same way we find that

$$\left. \begin{aligned} A_6 &= -0.0739A_0, \\ A_8 &= 0.00798A_0, \\ A_{10} &= -0.00058A_0. \end{aligned} \right\} \quad (9)$$

Using these numerical values in (7) leads to

$$1/A_0^2 = 3.9445, \quad \text{so } A_0 = 0.5035, \quad (10)$$

the positive sign being chosen. A more accurate value may be obtained by using  $a_0 = -10.6067292$ , starting at  $r = 6$  and working to, say, eight decimal places. Then  $A_0 = 0.5037681$ , so our approximate computation errs in the fourth significant figure. We can now

calculate the other  $A$ , using  $A_0$  at (10), and obtain

$$\left. \begin{aligned} A_2 &\simeq -0.668 \\ A_4 &\simeq 0.212 \\ A_6 &\simeq -0.037 \\ A_8 &\simeq 0.004 \\ A_{10} &\simeq -0.00029 \end{aligned} \right\} \begin{aligned} &-0.66791 \text{ 64, } \dagger \\ &0.21197 \text{ 32,} \\ &-0.03707 \text{ 27,} \\ &0.00400 \text{ 65,} \\ &-0.00029 \text{ 09.} \end{aligned} \quad (11)$$

Hence to a first approximation the first and periodic solution (cosine) of

$$y'' + (-10.6... - 16 \cos 2z)y = 0, \quad (12)$$

under the normalization of § 2.21, is

$$\begin{aligned} \text{ce}_0(z, 8) &= 0.504 - 0.668 \cos 2z + 0.212 \cos 4z - \\ &\quad - 0.037 \cos 6z + 0.004 \cos 8z - 0.0003 \cos 10z + \dots \end{aligned} \quad (13)$$

The graph of (13) is shown in Fig. 3.

*Checking the solution.* To check the solution at  $z = 0, \pi, \dots, n\pi$ , we have from the differential equation (12)

$$y''(n\pi) = (16 + 10.6...)y(n\pi). \quad (14)$$

From (13),

$$\begin{aligned} \text{ce}_0''(n\pi, 8) &\simeq 4 \times 0.668 - 16 \times 0.212 + 36 \times 0.037 - \\ &\quad - 64 \times 0.004 + 100 \times 0.0003 = 0.388, \end{aligned} \quad (15)$$

and

$$\begin{aligned} (26.6...) \text{ce}_0(n\pi, 8) &\simeq 26.6... (0.504 - 0.668 + 0.212 - \\ &\quad - 0.037 + 0.004 - 0.0003) = 0.391. \end{aligned} \quad (16)$$

The results in (15), (16) agree within 1 per cent., which is sufficient for purposes of illustration. The solution may be checked at any other point, e.g.  $z = \frac{1}{4}\pi$ .

*Remarks on the coefficients in (13).* There are two salient features: (a) beyond a certain term the coefficients decrease rapidly with increase in  $r$ , (b) they alternate in sign. (a) entails the rapid convergence of the series. For  $0 \leq q < 3.2$ , tabular values show that  $|A_0|$  is the largest coefficient, being  $2^{-\frac{1}{2}}$  at  $q = 0$ . When  $q > 3.2$  approximately,  $|A_2|$  takes precedence, e.g. in (13). The relative values of some of the early coefficients in the series for  $\text{ce}_2(z, 2)$ ,  $\text{se}_3(z, 2)$ ,  $\text{ce}_5(z, 2)$  are depicted in Fig. 6.

† The figures in this column are correct to seven decimal places [95].

**3.14. Evaluation of  $a_{2n}$  for  $ce_{2n}(z, q)$ ,  $n > 0$ .** Writing  $(r+1)$  for  $r$  in (4) § 3.11 and multiplying both sides by  $q/4r^2$ , we get [52]

$$-\frac{qv_{2r}}{4r^2} = [q^2/16r^2(r+1)^2] \left/ \left[ 1 - \frac{1}{4(r+1)^2}(a - qv_{2r+2}) \right] \right. \quad (1)$$

$$\begin{aligned} &= \frac{q^2/16r^2(r+1)^2}{1-a/4(r+1)^2} - \frac{q^2/16(r+1)^2(r+2)^2}{1-a/4(r+2)^2} - \frac{q^2/16(r+2)^2(r+3)^2}{1-a/4(r+3)^2} - \dots \\ &= E_{2r}. \end{aligned} \quad (2)$$

FIG. 6. Relative magnitudes of the coefficients in the series for  $ce_2(z, 2)$ ,  $se_3(z, 2)$ ,  $ce_5(z, 2)$ . For  $q = 2$ , the coefficient of functional order is the greatest.

If  $a = a_{2n}$ , the characteristic number for  $ce_{2n}(z, q)$ ,  $q \neq 0$ , none of the denominators in the components of (2) vanish. Then the C.F. is convergent, since the denominator of the general term approaches unity and the numerator tends to zero as  $r \rightarrow +\infty$ .

We shall now derive an alternative terminating C.F. to represent the l.h.s. of (1). After division by  $4r^2$ , the recurrence formula prior to (4) § 3.11 may be written

$$-\frac{qv_{2r}}{4r^2} = 1 - \frac{a}{4r^2} + \frac{q/4r^2}{v_{2r-2}} \quad (3)$$

$$= 1 - \frac{a}{4r^2} + \frac{q^2/16r^2(r-1)^2}{qv_{2r-2}/4(r-1)^2} \quad (r \geq 2). \quad (4)$$

Now write  $(r-1)$  for  $r$  in (4), thereby obtaining a formula for  $-qv_{2r-2}/4(r-1)^2$ . Substituting this in the third member on the r.h.s. of (4), we get

$$\begin{aligned} -\frac{qv_{2r}}{4r^2} &= 1 - \frac{a}{4r^2} - \\ &\quad - [q^2/16r^2(r-1)^2] \left/ \left[ 1 - [a/4(r-1)^2] + \frac{q^2/16(r-1)^2(r-2)^2}{qv_{2r-4}/4(r-2)^2} \right] \right. \end{aligned} \quad (5)$$

Continuing this process leads to the terminating C.F.

$$-\frac{qv_{2r}}{4r^2} = 1 - \frac{a}{4r^2} - \frac{q^2/16r^2(r-1)^2}{1-a/4(r-1)^2} - \frac{q^2/16(r-1)^2(r-2)^2}{1-a/4(r-2)^2} - \cdots + \frac{q^2/64}{qv_2/4}. \quad (6)$$

Since  $v_0 = a/q$  by (1) § 3.10, (2) § 3.11 may be written

$$\frac{1}{4}qv_2 = -(1 - \frac{1}{4}a + q^2/2a). \quad (7)$$

Substituting from (7) into (6) gives

$$-\frac{qv_{2r}}{4r^2} = 1 - \frac{a}{4r^2} - F_{2r}, \quad (8)$$

where

$$F_{2r} = \frac{q^2/16r^2(r-1)^2}{1-a/4(r-1)^2} - \frac{q^2/16(r-1)^2(r-2)^2}{1-a/4(r-2)^2} - \cdots - \frac{q^2/64}{1-a/4} + \frac{q^2}{2a}. \quad (9)$$

For the recurrence relations (1) § 3.10 to be consistent, (2) and (8) must be equal, so

$$E_{2r} = 1 - a/4r^2 - F_{2r}, \quad (10)$$

and for convenience in computation we may write

$$G_{2r} = 1 - a/4r^2 - E_{2r} - F_{2r} \quad (r \geq 1). \quad (11)$$

The appropriate value of  $a$  corresponds to  $G_{2r} = 0$ . To obtain  $a_2$ ,  $a_4, \dots$  for  $ce_2$ ,  $ce_4, \dots$  we use (11) with  $r = 1, 2, 3, \dots$  initially.

**3.15. Evaluation of  $a_4$  for  $ce_4(z, 8)$ .** To start the computation we have to find a trial value of  $a_4$ . By (9) § 2.151,  $a_4 = 16$  when  $q = 0$ , and increases with increase in  $q$ , so let us assume that  $a = 20$  for  $q = 8$ . In the r.h.s. of (4) § 3.14 take  $r = 2$ , substitute for  $\frac{1}{4}qv_2$  from (7) § 3.14, and we get

$$1 - \frac{1}{16}a - [(q^2/64)/(1 - \frac{1}{4}a + q^2/2a)] = 1 - \frac{1}{16}a - F_4 \quad (r = 2). \quad (1)$$

The first two members in (2) § 3.14 give

$$E_4 \simeq \frac{1/9}{1 - a/36} - \frac{1/36}{1 - a/64}. \quad (2)$$

Then (1) is approx. 0.166 while (2) is approx. 0.271, so

$$G_4 = 0.166 - 0.271 \simeq -0.105.$$

Examination of the formulae in § 3.14 indicates that  $a_4 < 20$ , so we now try  $a_4 = 19$  and obtain 0.297 for (1) and 0.26 for (2), i.e.  $G_4 \simeq +0.037$ . Thus the value of  $a_4$  lies between 19 and 20. By linear interpolation (see Fig. 7A),  $a_4 \simeq 19 + x = 19.26$ . Using this value in (1), (2) yields 0.261, 0.263 respectively, so  $G_4 \simeq -0.002$ .

A second linear interpolation gives  $a_4 \simeq 19.253$ . If now, with this value of  $a_4$ , we take  $r = 7$  in (2), (9) § 3.14 and repeat the computation, the value of  $a_4$  correct to seven decimal places is found to be 19.25270 51.

FIG. 7 (A, B). Illustrating linear interpolation.

**3.16. Evaluation of coefficients for  $ce_4(z, 8)$ .** By the first recurrence relation in (1) § 3.10

$$v_0 = A_2/A_0 = a_4/q = 19.25271/8 \simeq 2.4066. \quad (1)$$

From (7) § 3.14,

$$\begin{aligned} v_2 &= A_4/A_2 = -4(1 - \frac{1}{4}a - q^2/2a)/q \\ &= -(1 - 4.8132 + 1.6624)/2 \\ &= 1.0754. \end{aligned} \quad (2)$$

(3) § 3.14 may be expressed in the form

$$v_{2r} = \frac{1}{q}(a - 4r^2) - \frac{1}{v_{2r-2}} \quad (r \geq 2), \quad (3)$$

$$\text{so } v_4 = A_6/A_4 = 2.4066 - 2 - 0.9298 \quad (r = 2) \\ = -0.5232, \quad (4)$$

$$v_6 = A_8/A_6 = 2.4066 - 4.5 + 1.9113 \quad (r = 3) \\ = -0.1821, \quad (5)$$

$$v_8 = A_{10}/A_8 = 2.4066 - 8 + 5.4915 \quad (r = 4) \\ = -0.1019.^\dagger \quad (6)$$

As the computation proceeds, it becomes evident that  $v_{2r}$  is the small difference between two comparatively large numbers. For reasonable accuracy, therefore, it is imperative to use more decimal places than we have had hitherto. However, our purpose is merely to illustrate the method of computation, not to attain high accuracy, so we shall now evaluate the coefficients in accordance with the normalization of § 2.21. Following the routine in § 3.13, we find that

$$\left. \begin{aligned} A_2 &= 2.4066A_0, \\ A_4 &= 2.589A_0, \\ A_6 &= -1.355A_0, \\ A_8 &= 0.247A_0, \\ A_{10} &= -0.0245A_0. \end{aligned} \right\} \quad (7)$$

Then by § 2.21

$$1/A_0^2 = 2 + (A_2/A_0)^2 + (A_4/A_0)^2 + (A_6/A_0)^2 + \dots + \\ + (A_{10}/A_0)^2 + \dots \simeq 16.392, \quad (8)$$

$$\text{so } A_0 = 0.247. \quad (9)$$

We now calculate

$$\left. \begin{aligned} A_2 &= 0.595, \\ A_4 &= 0.639, \\ A_6 &= -0.335, \\ A_8 &= 0.061, \\ A_{10} &= -0.00606. \end{aligned} \right\} \quad (10)$$

The signs of the coefficients are in accordance with the remarks at the end of § 3.33. Inserting these coefficients in (1) § 2.17, the first solution of

$$y'' + (19.2527\dots - 16 \cos 2z)y = 0, \quad (11)$$

to a first approximation, is the periodic function

$$\text{ce}_4(z, 8) = 0.247 + 0.595 \cos 2z + 0.639 \cos 4z - \\ - 0.335 \cos 6z + 0.061 \cos 8z - 0.0061 \cos 10z + \dots \quad (12)$$

† The value of  $v_8$  correct to five decimal places is 0.09971.

Check on the solution. By (14) § 3.13, we have

$$y''(n\pi) \simeq (16 - 19.253)y(n\pi) = -3.253y(n\pi). \quad (13)$$

Now  $ce_4''(n\pi, 8) = -3.85$ , and  $-3.253 ce_4(n\pi, 8) = -3.9$ , so the agreement is of the order 1 per cent. To better this, it would be necessary to give the values of the coefficients to more than three decimal places.

**3.20. Characteristic numbers and coefficients for  $ce_{2n+1}$ ,  $se_{2n+1}$ ,  $se_{2n+2}$ .** These may be calculated in a similar way to those for  $ce_{2n}$ , using appropriate formulae derived from (2)-(4) § 3.10.

For  $ce_{2n+1}$ , with  $v_{2r+1} = A_{2r+3}^{(2n+1)}/A_{2r+1}^{(2n+1)}$ ,

$$v_1 = (a - 1 - q)/q, \quad (1)$$

$$-v_{2r-1} = [q/(2r+1)^2]/[1 - a/(2r+1)^2 + qv_{2r+1}/(2r+1)^2] \quad (r \geq 2). \quad (2)$$

For  $se_{2n+1}$ , with  $v_{2r+1} = B_{2r+3}^{(2n+1)}/B_{2r+1}^{(2n+1)}$ ,

$$v_1 = (a - 1 + q)/q, \quad (3)$$

$$-v_{2r-1} = \text{as at (2) above.} \quad (4)$$

For  $se_{2n+2}$ , with  $v_{2r} = B_{2r+2}^{(2n+2)}/B_{2r}^{(2n+2)}$ ,

$$v_2 = (a - 4)/q, \quad (5)$$

$$-v_{2r-2} = (q/4r^2)/[1 - a/4r^2 + qv_{2r}/4r^2] \quad (r \geq 3). \quad (6)$$

**3.21. Convergence of series for  $ce_m(z, q)$ ,  $se_m(z, q)$ .** The third relation at (1) § 3.10 is a linear difference equation. Writing  $(r+1)$  for  $r$ , we get

$$[a - 4(r+1)^2]A_{2r+2} - q(A_{2r+4} + A_{2r}) = 0. \quad (1)$$

Dividing throughout by  $A_{2r}$  and putting  $v_{2r} = A_{2r+2}/A_{2r}$ , gives

$$[a - 4(r+1)^2]v_{2r} - q(v_{2r+2}v_{2r} + 1) = 0, \quad (2)$$

so 
$$v_{2r+2} + \frac{1}{v_{2r}} = [a - 4(r+1)^2]q^{-1}. \quad (3)$$

Then  $v_{2r+2} + \frac{1}{v_{2r}} \rightarrow -\infty$  monotonically as  $r \rightarrow +\infty$ , and it is evident that  $v_{2r}$  cannot: (1) oscillate boundedly, (2) tend to a unique *finite* limit other than zero. Hence either  $v_{2r} \rightarrow 0$  or  $|v_{2r}| \rightarrow \infty$ . Now for convergence of the series representing  $ce_{2n}(z, q)$ ,  $A_{2r} \rightarrow 0$  as  $r \rightarrow +\infty$ , so  $v_{2r}$  must also tend to zero. Consequently, as  $r \rightarrow +\infty$ , one solution of (1) tends to zero, and the other to infinity. In the present instance the latter solution is inadmissible. Thus in (2), when  $r$  is large enough,  $v_{2r+2}v_{2r} \ll 1$ ,  $a \ll 4(r+1)^2$ , and with  $a, q$  finite

$$|v_{2r}| \sim q/4(r+1)^2 \rightarrow 0 \quad \text{as } r \rightarrow +\infty. \quad (4)$$

If  $z$  is real,  $|\cos 2rz| \leq 1$ , so it follows by the 'M' test that the series for  $ce_{2n}(z, q)$  is absolutely and uniformly convergent. Moreover, it represents a continuous function for all  $z$  real.

In like manner the series for  $ce_{2n+1}(z, q)$ ,  $se_m(z, q)$  may be proved to have the above properties. Hence all ordinary Mathieu functions are continuous for  $z$  real, and the series may be differentiated or integrated term by term provided the resulting series are uniformly convergent. This can be proved to be true. These conclusions apply to the series for  $q < 0$ .

**3.22. Convergence of series for  $ce_m^{(p)}(z, q)$ ,  $se_m^{(p)}(z, q)$ .** The  $p$ th derivative of  $ce_{2n}(z, q)$  is

$$\frac{d^p}{dz^p} [ce_{2n}(z, q)] = \sum_{r=1}^{\infty} (2r)^p A_{2r} \left. \begin{array}{l} (-1)^{1p} \cos 2rz \\ (-1)^{\frac{1}{2}(p+1)} \sin 2rz \end{array} \right\} \begin{array}{l} p \text{ even,} \\ p \text{ odd.} \end{array} \quad (1)$$

Thus the ratio of the coefficients of the  $(r+1)$ th and  $r$ th terms is

$$\left| \frac{u_{r+1}}{u_r} \right| = \left( \frac{r+1}{r} \right)^p |v_{2r}| = (1 + 1/r)^p |v_{2r}|. \quad (2)$$

Then by (4) § 3.21,

$$|u_{r+1}/u_r| \rightarrow 0 \quad \text{as } r \rightarrow +\infty, \quad (3)$$

so all derivatives of  $ce_{2n}(z, q)$  are absolutely and uniformly convergent for  $z$  real. The same conclusion may be reached in connexion with  $ce_{2n+1}(z, q)$ ,  $se_m(z, q)$  by similar analysis. This, and proof of the validity of term-by-term integration, are left as exercises for the reader.

**3.23. Convergence of series for  $Ce_m(z, q)$ ,  $Se_m(z, q)$ , and derivatives.** The series are merely those for  $ce_m(z, q)$ ,  $se_m(z, q)$  with  $zi$  written for  $z$ . Hence, by (2) § 2.30 and (4) § 3.21,

$$\left| \frac{u_{r+1}}{u_r} \right| \sim \frac{q}{4(r+1)^2} \frac{\cosh(2r+2)z}{\cosh 2rz}. \quad (1)$$

In § 3.21 we proved that the series for  $ce_{2n}(z, q)$  is absolutely and uniformly convergent for all  $z$  real. Hence the series for  $Ce_{2n}(z, q)$  conforms to this when  $z$  is imaginary, i.e.  $R(z) = 0$ . Now when  $R(z) \neq 0$ , from (1),

$$\left| \frac{u_{r+1}}{u_r} \right| \sim qe^{2|z|}/4(r+1)^2 \rightarrow 0 \quad \text{as } r \rightarrow +\infty \quad (2)$$

provided  $R(z)$  is finite. Hence the series for  $Ce_{2n}(z, q)$  is absolutely convergent under this condition. By applying the 'M' test it may

be proved uniformly convergent. Hence the series is absolutely and uniformly convergent in any finite region of the  $z$ -plane or in any closed interval of  $z$  real. The same result may be reached for the three remaining functions, and for the  $p$ th derivatives of all four functions (see § 3.22).

**3.24. Characteristic curves for  $ce_m(z, \pm q)$ ,  $se_m(z, \pm q)$ ,  $q$  real.** There are tabular values of  $a_0, a_1, \dots, a_5$  and  $b_1, b_2, \dots, b_6$  in the range  $q = 0-40$ , given in Appendix 2 [95]. When these are plotted using cartesian coordinates, the chart of Fig. 8 A is obtained [88]. It is symmetrical about the  $a$ -axis.  $a_{2n}, b_{2n+2}$ , the characteristic curves for  $ce_{2n}, se_{2n+2}$  respectively, are symmetrical about this axis, but  $a_{2n+1}, b_{2n+1}$  corresponding to  $ce_{2n+1}, se_{2n+1}$  are asymmetrical. Nevertheless the symmetry of the diagram is maintained, since the curves for the functions of odd order, i.e.  $a_{2n+1}, b_{2n+1}$  are mutually symmetrical, e.g.  $a_3, b_3$ . When  $q$  is positive and large enough, the curves  $a_{2n}, b_{2n+1}$  approach and are mutually asymptotic, but have no independent linear asymptote. A similar remark pertains to  $a_m, b_{m+1}$ . When  $q$  is negative and large enough,  $a_{2n} \sim a_{2n+1}$ , and  $b_{2n+1} \sim b_{2n+2}$ . It should be noted that of the corresponding pairs of functions one has period  $\pi$ , the other period  $2\pi$ .

Excepting the curve  $a_0$ , which is tangential to the  $q$ -axis at the origin in Fig. 8 A, B, all curves intersect this axis twice, one value of  $q$  being positive, the other negative. Thus each characteristic has two real zeros in  $q$ . For the functions of even order  $ce_{2n}, se_{2n+2}$ , the zeros are equal but opposite. The zeros of  $ce_{2n+1}$  are equal but opposite to those of  $se_{2n+1}$ . Since Mathieu's equation has only one solution of type  $ce_m$  or  $se_m$  ( $q \neq 0$ ), two characteristic curves cannot intersect.

Approximate values of  $q \geq 0$  for which  $a$  is zero are given in Table 1.

TABLE 1. Zeros in  $q \geq 0$  of  $a_m, b_m$

Characteristic number	$a_0$	$b_1$	$a_1, b_2$	$a_2, b_3$	$a_m, b_{m+1}, m \geq 3$
Value of $q$	0	0.88	7.5 $\frac{1}{7}$	21.28	0.86(2m+1) $^{\dagger}$

For  $m \geq 3$ , the  $q$  interval between the zeros of  $a_m$  and  $a_{m+1}$  is 6.88(m+1).

$^{\dagger}$  This formula was obtained by taking several terms of (1) § 11.44, putting  $a = 0$  and solving for  $q$ .

**3.25. Continuity of the characteristic numbers as functions of  $q$ .** By considering successive convergents, it may be demonstrated

FIG. 8 (A). Stability chart for Mathieu functions of integral order. The characteristic curves  $a_0, b_1, a_1, b_2, \dots$  divide the plane into regions of stability and instability. The even-order curves are symmetrical, but the odd-order curves are asymmetrical about the  $a$ -axis. Nevertheless the diagram is symmetrical about the  $a$ -axis.

that the continued fractions for computing the  $a$  (see §§ 3.11, 3.14, 3.15) may be expressed as the quotient of two integral functions. The denominator of this quotient cannot vanish if the value of  $a$  is a characteristic number for a periodic Mathieu function of integral

order. Hence the continued fraction is continuous for any pair of values  $(a, q)$  which satisfy the relationship regarded as a transcendental equation for  $a$ . It follows, therefore, that  $a_m, b_m$ , the characteristic numbers for  $ce_m, se_m$ , are continuous† functions of  $q$ . Since the transcendental equations for the  $a$  are derived primarily

Fig. 8 (B). Illustrating variation in the parameter  $\sigma$  in stable and unstable regions  $q > 0$  and  $q < 0$ .  $a_m, b_{m+1}$  are mutually asymptotic and  $\rightarrow -\infty$  as  $q \rightarrow +\infty$ .  $a_m, a_{m+1}; b_m, b_{m+1}$  are mutually asymptotic and  $\rightarrow -\infty$  as  $q \rightarrow -\infty$  (see § 12.30).

from the recurrence relations, the coefficients  $A_m, B_m$  are continuous† functions of  $q$  (see Fig. 9).

**3.26. Additional comments on normalization.** We are now able to comment upon the normalization of § 2.11, where the coefficient of  $\cos mz$  in  $ce_m(z, q)$ , and that of  $\sin mz$  in  $se_m(z, q)$  is unity for all values of  $q$ . We shall show that under this convention the remaining coefficients are infinite for certain values of  $q \neq 0$  [52].

Consider  $ce_2(z, q)$  whose characteristic number is  $a_2$ . Then (1) § 3.10 gives

$$q/a_2 = A_0/A_2. \quad (1)$$

† And single-valued.

Now by § 3.24,  $a_2 = 0$  for  $q_2 \simeq \pm 21.28$ , so  $A_0/A_2$  is then infinite, and since  $A_2 = 1$ ,  $A_0 = \infty$ . Also with  $a_2 = 0$  in the second formula in (1) § 3.10 we have

$$2qA_0 + 4A_2 + qA_4 = 0, \quad (2)$$

and since  $A_0 = \infty$ ,  $A_2 = 1$ ,  $q \neq 0$ , we get  $A_4 = -\infty$ , and so on. Thus when  $q_2 \simeq \pm 21.28$ ,  $a_2 = 0$ , and all the coefficients except  $A_2$  become infinite.

A similar conclusion may be reached for the coefficients of any Mathieu function of integral order, excepting  $ce_0$ ,  $ce_1$ ,  $se_1$ ,  $se_2$ . We shall now examine these singular cases. For  $ce_0$ , (1) § 3.10 gives

$$A_0/A_2 = q/a_0. \quad (3)$$

Since  $A_0 = 1$  for all  $q$ , and  $a_0$  never vanishes in  $q > 0$ ,  $A_2$  is always finite. It is shown in § 12.30 that  $a_0 \sim -2q$  as  $q \rightarrow \pm\infty$ , so  $A_0/A_2 \rightarrow -\frac{1}{2}$  as  $q \rightarrow +\infty$ . By employing the second recurrence formula for  $ce_0$ , we can demonstrate that  $A_4$  is finite, and so on.

For  $ce_1$ , (2) § 3.10 gives

$$A_1/A_3 = q/(a_1 - 1 - q), \quad (4)$$

and since  $A_1 = 1$  for all  $q$ , while by Appendix 2  $(a_1 - 1 - q) \neq 0$  in  $q > 0$ ,  $A_3$  cannot become infinite. Since  $a_1 \sim -2q$  as  $q \rightarrow +\infty$ ,  $A_1/A_3 \rightarrow -\frac{1}{3}$ . The functions  $se_1$ ,  $se_2$  are amenable to similar treatment.

Apart from the above exceptions, it appears—although we have not given a general proof—that for functions of order  $2n$ ,  $2n+1$  there are  $n$  values of  $q > 0$ , and an equal number for  $q < 0$ , for which all coefficients, save that of the same order as the function, become infinite. The positive and negative  $q$  are equal numerically. We see, therefore, that the convention of § 2.11 is inadmissible for general purposes, although it is sometimes useful when  $q$  is small, and series for  $ce_m$ ,  $se_m$  are given in ascending powers of  $q$  (§ 2.13 et seq.). Accordingly we shall now enumerate the advantages of the convention of § 2.21, which is based upon the orthogonal properties of the Mathieu functions.

### 3.27. Advantages of the normalization of § 2.21.

1°. By (2), (4) § 2.21, none of the coefficients is infinite for any  $q$ .

2°. When  $q \rightarrow 0$ , it is shown in § 3.32 that the coefficient of the same order as the function tends to unity,† while the remainder tend to zero.‡ Hence  $ce_m(z, q) \rightarrow \cos mz$ ,  $se_m(z, q) \rightarrow \sin mz$ , and these

† Except  $A_0^{(0)}$  for  $ce_0$  which as shown in § 2.21 is  $2^{-1}$ . In this section  $m > 0$ .

‡ As stated in § 3.32, this is independent of the normalization.

are the formal solutions of  $y'' + ay = 0$ ,  $a = m^2$ , which is Mathieu's equation with  $q = 0$ . The vanishing of the coefficients entails  $A_{2n}/A_0$ ,  $A_{2n+1}/A_1$ , etc., being infinite, but this is inconsequential.

3°. The integrals at (1) § 2.21 are independent of  $q$  (real).

4°. The mean square value of the function for the interval  $(0-2\pi)$  is the same as that of  $\cos mz$ ,  $\sin mz$ , i.e.  $\frac{1}{2}$ .

### 3.30. Properties of the $A, B$ under the normalization of § 2.21.

Referring to (12) § 3.16, we see that (a) beyond a certain term the

FIG. 9. Illustrating  $A_0^{(2)}, \dots, A_{10}^{(2)}$  as single-valued continuous functions of  $q \geq 0$ . When  $q \rightarrow 0$ ,  $A_0 \propto q$ ,  $A_2 \rightarrow 1$ ,  $A_4 \propto q$ ,  $A_6 \propto q^2$ , and so on.

$A$  decrease rapidly in numerical value with increase in  $r$ , (b) after the term in  $\cos 4z$ , they alternate in sign, (c)  $|A_4|$  is the largest, but this depends upon the value of  $q$ , e.g.  $|A_2| > |A_4|$  when  $q = 9$ . The values of the  $A, B$  vary with  $q$ , and by § 3.25 the variation is continuous in  $q \geq 0$ . This is illustrated in Fig. 9 by data from [52, 95]. In the range  $0 < q \leq 40$ , tabular data show that  $A_2^{(2)}, A_3^{(3)}, A_4^{(4)}, A_5^{(5)}, B_4^{(4)}, B_5^{(5)}, B_6^{(6)}$  each have one zero in  $q$ .  $B_3^{(3)}$  has a zero in  $q > 40$ .

1°. *Coefficients in series for*  $ce_0, ce_1, se_1, se_2$ . For  $ce_0$ , (1) § 3.10 gives

$$A_2/A_0 = a_0/q. \quad (1)$$

From Fig. 8,  $a_0$  is negative in  $q > 0$ , so the r.h.s. of (1) is negative also. By § 3.27,  $A_0, A_2$  are finite, so neither has a zero in  $q > 0$ . From the first two relations in (1) § 3.10, we get

$$A_4/A_2 = [(a_0 - 4)/q] - 2q/a_0. \quad (2)$$

Thus  $A_4/A_2$  will not vanish in  $q > 0$  provided  $a_0(a_0 - 4) > 2q^2$ . Tabular values show that  $A_4/A_2$  does not vanish in  $0 < q \leq 1600$  [52]. Beyond this range we take  $a_0 \sim -2(q - q^{\frac{1}{2}})$  from (7) § 12.30 and find that the above inequality is satisfied. Hence  $A_4$  has no zero in  $q > 0$ . Similarly it may be shown that the remaining  $A$  have no zeros in  $q > 0$ . This conclusion is valid for the coefficients in the series for  $ce_1, se_1, se_2$ . It is confirmed up to  $q = 1600$  by tabular values in [52].

2°. *Real zeros of*  $A_{2r}^{(2n)}, A_{2r+1}^{(2n+1)}, B_{2r+1}^{(2n+1)}, B_{2r+2}^{(2n+2)}$  in  $q > 0, n > 0$ . For  $ce_{2n}$ , (1) § 3.10 gives

$$A_2/A_0 = a_{2n}/q. \quad (1)$$

When  $n > 0$ ,  $a_{2n}$  vanishes once in  $q > 0$  (see Fig. 8), and since by § 3.27  $A_0$  is finite, and by (1) above it has no zero in  $q > 0$ ,  $A_2 = 0$  when  $a_{2n} = 0$ . With  $q$  large enough, by (7) § 12.30  $a_{2n} \sim -2q + (8n + 2)q^{\frac{1}{2}}$ , so  $A_2/A_0 \rightarrow -2$  as  $q \rightarrow +\infty$ , and  $A_0$  never vanishes in  $q > 0$ . From (1) § 3.10 we obtain

$$A_4/A_2 = -(2q^2 + 4a_{2n} - a_{2n}^2)/qa_{2n}. \quad (2)$$

Then at the two intersections of  $2q^2 + 4a_{2n} - a_{2n}^2$ , and the curve  $a_{2n}$  ( $q > 0$ ), we get

$$A_4/A_2 = 0. \quad (3)$$

Hence  $A_4$  vanishes twice in  $q > 0$ . Proceeding thus we find that  $A_6$  vanishes thrice in  $q > 0$ , and so on. The coefficients for other functions may be treated in a similar way.

The zeros of some of the  $A$  in  $ce_2$  are given in Table 2. The second zero of  $A_4^{(2)}$ , the second and third of  $A_6^{(2)}$ , and all four of  $A_8^{(2)}$  lie beyond  $q = 1600$ . Tabular data indicate that the coefficient of equal order with the function has the smallest zero in  $q$ .

TABLE 2

Coefficient	First zero in $q$ (approx.)
$A_3^{(2)}$	21.28
$A_4^{(2)}$	373.6
$A_6^{(2)}$	1352.8
$A_8^{(2)}$	> 1600

Although we have not given a general proof, under the normalization of § 2.21 it appears that if  $n > 0$ ,  $A_{2r}^{(2n)}$ ,  $A_{2r+1}^{(2n+1)}$ ,  $B_{2r+1}^{(2n+1)}$ ,  $B_{2r+2}^{(2n+2)}$  each has  $r$  real zeros in  $q > 0$ . These correspond to the infinities under the normalization of § 2.11 (see § 3.26). It may be shown that when  $r = 0$  none of the above coefficients has a zero in  $q > 0$ .

**3.31. Numerical check on § 3.30.** The values of  $q$  at the intersections of the straight lines or curves for a null numerator, e.g. as in 2° § 3.30, where  $2q^2 + 4a_{2n} - a_{2n}^2 = 0$ , and the appropriate characteristic curves  $a_m$ ,  $b_m$  (Fig. 8), were calculated for several functions and are given in Table 3. They are in satisfactory agreement with the zeros in  $q$  of the coefficients  $A$ ,  $B$  computed by interpolation from tabular values. The limited range of  $q$  in the tables permitted checking of the first zeros only.

TABLE 3. *Approximate zeros in  $0 < q \leq 40$  of  $A_m^{(m)}$ ,  $B_m^{(m)}$*

$m$	$A_m^{(m)}$ for $ce_m(z, q)$				$B_m^{(m)}$ for $se_m(z, q)$			
	2	3	4	5	3	4	5	6
$q$	21.28	15.6	17.4	20.7	> 40	37.3	31.4	31.8

$A_0^{(0)}$ ,  $A_1^{(1)}$ ,  $B_1^{(1)}$ ,  $B_2^{(2)}$  have no zeros in  $q > 0$ .

**3.32. Behaviour of coefficients as  $q \rightarrow 0$ .** From (1) § 3.10 for  $ce_2(z, q)$

$$A_0 \simeq A_2 q/4, \quad (1)$$

and since  $A_2$  is finite,  $A_0 \rightarrow 0$  as  $q \rightarrow 0$ . Also

$$(a_2 - 4)A_2 = q(2A_0 + A_4). \quad (2)$$

Substituting for  $a_2$  from (5) § 2.151, and for  $A_0$  from (1) into (2), gives

$$[\frac{5}{12}q^2 + O(q^4)]A_2 = \frac{1}{2}q^2 A_2 + qA_4, \quad (3)$$

so when  $q$  is small

$$A_4 \simeq -\frac{1}{12}q A_2 \rightarrow 0 \quad \text{as } q \rightarrow 0. \quad (4)$$

Again by (1) § 3.10 with  $r = 2$ ,

$$(a_2 - 16)A_4 = q(A_2 + A_6), \quad (5)$$

and by (5) § 2.151 and (4) above

$$-\frac{1}{12}A_2[-12 + O(q^2)] = A_2 + A_6. \quad (6)$$

Thus when  $q \rightarrow 0$ ,  $A_6 \rightarrow 0$ , and so on for the other coefficients. Now using (2) § 2.21, it follows from above that

$$A_2^{(2)} \rightarrow 1 \quad \text{as } q \rightarrow 0. \quad (7)$$

In a similar way it may be demonstrated that in (1)–(4) § 2.17,  $A_m^{(m)} \rightarrow 1$ ,  $B_m^{(m)} \rightarrow 1$  when  $q \rightarrow 0$ , while all the other  $A$ ,  $B$  tend to zero. The latter result depends upon the recurrence relations, and is independent of the normalization.

**3.33. Form of coefficients when  $q$  is small.** By solving Mathieu's equation as shown in § 2.13 et seq. or alternatively, the following results may be derived [215]:

$$A_{2r}^{(0)} = (-1)^r \left[ \frac{2}{(r!)^2} t^r - \frac{2r(3r+4)}{[(r+1)!]^2} t^{r+2} + O(t^{r+4}) \right] A_0^{(0)}, \quad t = \frac{1}{4}q \quad (r \geq 1); \quad (1)$$

$$A_{2r+1}^{(1)} = (-1)^r \left[ \frac{1}{r!(r+1)!} t^r + \frac{r}{[(r+1)!]^2} t^{r+1} + \frac{1}{4(r-1)!(r+2)!} t^{r+2} + \right. \\ \left. + O(t^{r+3}) \right] A_1^{(1)}; \quad (2)$$

$$A_0^{(2)} = \left[ t - \frac{5}{3} t^3 + \frac{1363}{216} t^5 + O(t^7) \right] A_2^{(2)}; \quad (3)$$

$$A_{2r+2}^{(2)} = (-1)^r \left[ \frac{2}{r!(r+2)!} t^r + \frac{r(47r^2+222r+247)}{18(r+2)!(r+3)!} t^{r+2} + O(t^{r+4}) \right] A_2^{(2)}; \quad (4)$$

$$B_{2r+1}^{(1)} = (-1)^r \left[ \frac{1}{r!(r+1)!} t^r - \frac{r}{[(r+1)!]^2} t^{r+1} + \frac{1}{4(r-1)!(r+2)!} t^{r+2} + \right. \\ \left. + O(t^{r+3}) \right] B_1^{(1)}; \quad (5)$$

$$B_{2r+2}^{(2)} = (-1)^r \left[ \frac{2}{r!(r+2)!} t^r - \frac{r(r+1)(7r+23)}{18(r+2)!(r+3)!} t^{r+2} + O(t^{r+4}) \right] B_2^{(2)}. \quad (6)$$

Either by obtaining formulae similar to (1)–(6) or by using recurrence relations, and the expansions of  $a$  in terms of  $q$ , it may be deduced that if  $q$  is small enough,  $A_{2r}^{(2n)}$ ,  $A_{2r+1}^{(2n+1)}$ ,  $B_{2r+1}^{(2n+1)}$ ,  $B_{2r+2}^{(2n+2)}$ , are  $O(q^{n-r})$  or  $O(q^{r-n})$  according as  $n \leq r$ . To illustrate this point, we find for  $\text{ce}_5(z, q)$  that when  $q$  is small enough, the recurrence relations give

$$A_1^{(5)} \simeq \frac{1}{384} q^2 A_5^{(5)}, \quad A_3^{(5)} \simeq \frac{1}{16} q A_5^{(5)}, \quad A_5^{(5)} \simeq 1,$$

$$A_7^{(5)} \simeq -\frac{1}{24} q A_5^{(5)}, \quad \text{and} \quad A_9^{(5)} \simeq \frac{1}{1344} q^2 A_5^{(5)}.$$

Since  $\sum_{r=0}^{\infty} [A_{2r+1}^{(5)}]^2 = 1$ , we obtain

$$A_5^{(5)} \simeq 1 - \frac{13}{4608} q^2 + O(q^4). \quad (7)$$

From [28] we get the general formulae ( $r \geq 0, m > 0$ ),

$$A_{m+2r}^{(m)} \simeq (-1)^r \frac{m!}{r! (m+r)!} t^r, \quad (8)$$

and

$$A_{m-2r}^{(m)} \simeq \frac{(m-r-1)!}{r! (m-1)!} t^r. \quad (9)$$

The results in (7) agree with those obtained from (8), (9). When  $q$  is not too large, we infer from (8) that the  $A$  of order greater than  $m$  are alternately negative and positive, while (9) shows that all those of order less than  $m$  are positive.  $A_m^{(m)}$  is positive. These statements are borne out by tabular values, from which they are seen to be invalid when  $q$  exceeds a certain value [95].

**3.34. Behaviour of coefficients as  $q \rightarrow +\infty$ .** We use the recurrence relations in § 3.10, and  $a \sim -2q$  from § 12.30. Then for  $ce_{2n}$ ,

$$aA_0 - qA_2 = 0, \quad (1)$$

so

$$A_2/A_0 \rightarrow -2 \quad \text{as } q \rightarrow +\infty. \quad (2)$$

Also

$$(a-4)A_2 - q(A_4 + 2A_0) = 0, \quad (3)$$

so substituting for  $a, A_2$ ,

$$-4A_0 + A_4 + 2A_0 = 0, \quad \text{giving } A_4/A_0 \rightarrow 2 \text{ as } q \rightarrow +\infty. \quad (4)$$

In general we find that

$$A_{2r}^{(2n)}/A_0^{(2n)} \rightarrow (-1)^r 2 \quad \text{as } q \rightarrow +\infty. \quad (5)$$

By (2) § 2.21 it follows that for  $n \geq 0$ , all the  $A^{(2n)} \rightarrow 0$  as  $q \rightarrow +\infty$ , in a manner compatible therewith. Similar analysis yields the same conclusion for the  $A^{(2n+1)}, B^{(m)}$ . The results corresponding to (5) are, for  $n \geq 0$ ,

$$A_{2r+1}/A_1 \rightarrow (-1)^r (2r+1); \quad B_{2r+1}/B_1 \rightarrow (-1)^r; \\ B_{2r+2}/B_2 \rightarrow (-1)^r (r+1). \quad (6)$$

*Numerical illustration.* When  $q = 1600$ , from [52],  $A_2/A_0 \simeq -1.95$  for  $ce_0$ , and  $-1.75$  for  $ce_2$ , as against  $-2$  as  $q \rightarrow +\infty$ . Using  $a \sim -2q + (8n+2)q^{\frac{1}{2}}$  from § 12.30 in the recurrence relations, we obtain  $-1.95, -1.75$  for  $q = 1600$ . For  $ce_1$ ,  $A_3/A_1 \simeq -2.85$ , and with the better asymptotic form of  $a$  we get  $-2.85$ . As  $q \rightarrow +\infty$ , the ratio  $\rightarrow -3$ . The accuracy of the values calculated in the above way decreases with increase in the order of the function.

$A_{2r}^{(2n)}$  as a function of  $q$ . By § 3.33 it is  $O(q^n)$  in the neighbourhood of  $q = 0$ , with  $p \geq 0$ ; by § 3.30 it has  $r$  real zeros in  $q > 0$ ; and from

above it tends to zero as  $q \rightarrow +\infty$ . Thus we surmise that in general  $A_{2r}^{(2n)}$  is an alternating non-periodic function of  $q$  which ultimately tends to zero asymptotically. The same conclusion pertains to the other coefficients.

**3.35. Behaviour of coefficients as  $n \rightarrow +\infty$ .** When  $a$  is very large, positive, and much greater than  $q$ ,  $a_{2n} \sim 4n^2$ . From (1) § 3.10

$$A_0/A_2 = q/a \sim q/4n^2 \rightarrow 0 \quad \text{as } n \rightarrow +\infty. \quad (1)$$

Hence  $A_0 \rightarrow 0$ . From (1) § 3.10

$$A_2/A_4 = q/(a-4) \rightarrow 0 \quad \text{as } n \rightarrow +\infty. \quad (2)$$

Hence  $A_2 \rightarrow 0$ . In like manner it can be shown that all the  $A \rightarrow 0$  except  $A_{2n}^{(2n)}$  which tends to unity. The same conclusion applies to the coefficients for the other functions of integral or fractional order.

**3.40. Solution of  $y'' + (a - 2q \cos 2z)y = 0$ , when  $q$  is negative imaginary.** In the problem of eddy current effects in § 17.10,  $q$  takes the form  $-is$ ,  $s$  being real and positive. In numerical work it is preferable to work with  $q = +is$ , and then obtain the solution for  $q = -is$  by writing  $(\frac{1}{2}\pi - z)$  for  $z$ . The value of  $a$  is real or complex according to conditions. For  $q$  moderate, the series for  $a_m, b_m$  in § 2.151 are convergent, and may be used for computation. The series for  $a_{2n}, b_{2n}$  proceed in powers of  $q^2$ , while those for  $a_{2n+1}, b_{2n+1}$  proceed in powers of  $q$ . Hence  $a_{2n}, b_{2n}$  are real, but  $a_{2n+1}, b_{2n+1}$  are complex. When  $s > s_0$ ,  $s_0$  depending upon  $n$  and the function,  $a_{2n}, b_{2n}$  are complex. In the sections following, the method of calculating characteristic numbers and coefficients is exemplified.

**3.41. Calculation of  $a_0$  and coefficients in the series for  $\text{ce}_0(z, -0.16i)$ .** We take  $s = 0.16$  in (1) § 2.151, so with  $q = is$

$$a_0 = \frac{1}{2}s^2 + \frac{7}{128}s^4 + \frac{29}{2304}s^6 + \dots \quad (1)$$

$$= 0.0128 + 0.00003584 + 0.00021$$

$$= 0.012836 \quad \text{to six decimal places.} \quad (2)$$

By (1) § 3.10,

$$\begin{aligned} v_0 &= A_2/A_0 = a_0/is = -0.012836i/0.16 \\ &= -0.080225i, \end{aligned}$$

so

$$A_2 = -0.080225iA_0. \quad (3)$$

From (2) § 3.11,

$$v_2 = (a_0 - 4 - 2q/v_0)/q \quad (4)$$

$$= [0.01283 \ 6 - 4 + (0.32i/0.08022 \ 5i)]/0.16i$$

$$= -0.01011 \ 2i. \quad (5)$$

Thus

$$\begin{aligned} A_4 &= -0.01011 \ 2iA_2 = -0.01011 \ 2 \times 0.08022 \ 5A_0 \\ &= -0.00081 \ 1A_0. \end{aligned} \quad (6)$$

Hence

$$ce_0(z, +0.16i) \simeq A_0[1 - 0.0802i \cos 2z - 0.0008 \cos 4z + \dots], \quad (7)$$

and by writing  $(\frac{1}{2}\pi - z)$  for  $z$  on the r.h.s. of (7),† we get

$$ce_0(z, -0.16i) \simeq A_0[1 + 0.0802i \cos 2z - 0.0008 \cos 4z + \dots]. \quad (8)$$

An approximate check on the  $A$  may be obtained by using the formula (6) § 2.150, namely,

$$\begin{aligned} ce_0(z, q) \simeq 1 - \left(\frac{1}{2}q - \frac{7}{128}q^3 + \dots\right) \cos 2z + \left(\frac{1}{32}q^2 - \frac{5}{1152}q^4 + \dots\right) \cos 4z - \\ - \left(\frac{1}{1152}q^3 - \dots\right) \cos 6z + \left(\frac{1}{73728}q^4 - \dots\right) \cos 8z + \dots \end{aligned} \quad (9)$$

$v_4 = A_6/A_4$  may be calculated by aid of (4) § 3.11 expressed in the form

$$v_{2r} = (a - 4r^2 - q/v_{2r-2})/q \quad (r \geq 2), \quad (10)$$

but the numbers involved are such that unless each is given to more decimal places than we have used above, a large error will occur. It is preferable to write (10) in the form

$$v_{2r-2} = q/(a - 4r^2 - qv_{2r}), \quad (11)$$

and as an approximation to assume that  $v_{2r}$  vanishes to an adequate number of decimal places. Then with  $r = 3$  in (11), we get

$$v_4 \simeq 0.16i/(0.0128 - 36) = -0.00444 \ 6i, \quad (12)$$

so

$$\begin{aligned} A_6 &= -0.00444 \ 6iA_4 = 0.00444 \ 6i \times 0.00081 \ 1A_0, \\ &= 0.00000 \ 36iA_0. \end{aligned} \quad (13)$$

To the same number of decimal places this value is obtained from (9), i.e.  $-q^3/1152$ , with  $q = 0.16i$ . The value of  $A_6$  in (7) is given at (13), but in (8) its sign will be negative.

† When the  $A$  are either real or imaginary, but not complex, (8) is obtained by changing the sign of  $i$  in (7).

**3.42.  $a_2$  and the  $A$  in the series for  $ce_2(z, -0.16i)$ .** From (5) § 2.151 we have, with  $q = is$ ,

$$a_2 = 4 - \frac{5}{12}s^2 - \frac{763}{13824}s^4 - \frac{10\ 02401}{796\ 26240}s^6 + \dots \quad (1)$$

$$= 4 - 0.01066\ 667 - 0.00003\ 617 - 0.0^6 21$$

$$= 3.98929\ 7. \quad (2)$$

Proceeding as in § 3.41, we find that

$$ce_2(z, 0.16i) = A_0[1 - 25i \cos 2z - 0.328 \cos 4z + 0.00164i \cos 6z + \dots] \quad (3)$$

and

$$ce_2(z, -0.16i) = A_0[1 + 25i \cos 2z - 0.328 \cos 4z - 0.00164i \cos 6z + \dots]. \quad (4)$$

When  $q$  is moderate and real,  $|A_{2n}|$  is the largest coefficient in the series for  $ce_{2n}(z, q)$ . This is true if  $q$  is moderate but imaginary, as is exemplified by the  $A$  in (4).

**3.43. Calculation of  $a_0$  and the  $A$  in  $ce_0(z, -4.8i)$ .** Here  $s = 4.8$ , which is too large for (1) § 3.41 to give an adequately accurate result. Instead of using this formula, we obtain an approximation to  $a_0$  by means of two asymptotic formulae. The first is (1) § 11.44, and for brevity we designate the r.h.s. by  $\Gamma_m$ . The second is in reference [56], and takes the form

$$b_{m+1} - a_m \sim \frac{2^{4m+5}}{m!} \left(\frac{2}{\pi}\right)^{\frac{1}{2}} q^{i(m+1)} e^{-4q^1} (1 + c_1 q^{-1} + c_2 q^{-1} + \dots) \equiv \Delta_m, \quad (1)$$

where  $c_1 = -0.225, -0.849, -1.765, -2.925$  correspond respectively to  $m = 0, 1, 2, 3$ , and the value of  $|q|$  is large enough for terms involving  $c_2, c_3, \dots$  to be neglected. In reference [57] it is explained that  $\Gamma_m - \frac{1}{2}\Delta_m$  is a suitable approximation to  $a$  for starting a computation, provided  $s$  is large enough. We take  $q = is$ ,  $s$  real and positive, and finally write  $(\frac{1}{2}\pi - z)$  for  $z$  in the  $ce_0(z, 4.8i)$  series, thereby obtaining that for  $ce_0(z, -4.8i)$ . In the formulae for  $\Gamma_m, \Delta_m$  we take  $\pm i = e^{\pm i\pi i}$ ,  $i^{\pm 1} = e^{\pm i\pi i}$ , and so on. Values for  $m = 0$  are given in Table 4 [57].

We commence the computation by assuming that the tabular value of  $a_0$  for  $s = 4.8$  is an adequate approximation, and apply the recurrence relation (4) § 3.11 in the form

$$v_{2r-2} = q/(a - 4r^2 - qv_{2r}) \quad (r \geq 2). \quad (2)$$

TABLE 4

$s$	$\Gamma_0$	$\Delta_0$	$\Gamma_0 - \frac{1}{2}\Delta_0 \simeq a_0$
1.6	1.52624 0 - 1.38491 6i	-0.56 - 0.68i	1.80624 0 - 1.04491 6i
3.2	2.26885 6 - 3.85346 8i	-0.2848 + 0.2132i	2.41125 6 - 3.96006 8i
4.8	2.83878 8 - 6.48850 8i	+0.0356 + 0.1528i	2.82098 8 - 6.56490 8i
6.4	3.31939 2 - 9.21146 8i	+0.07016 + 0.02744i	3.28431 2 - 9.22518 8i
8.0	3.74247 2 - 11.99053 6i	+0.03416 8 - 0.01775 6i	3.72538 8 - 11.98165 8i
9.6	4.12486 0 - 14.80972 0i	+0.00656 0 - 0.01960 8i	4.12158 0 - 14.79991 6i
11.2	4.47642 8 - 17.65937 2i	-0.00432 4 - 0.01071 2i	4.47859 0 - 17.66472 8i
12.8	4.80360 0 - 20.53316 8i	-0.00574 4 - 0.00336 8i	4.80647 2 - 20.53148 4i
14.4	5.11084 8 - 23.42672 0i	-0.00393 2 + 0.00033 0i	5.11281 4 - 23.42688 5i
16.0	5.40142 4 - 26.33682 0i	-0.00178 0 + 0.00148 8i	5.40231 4 - 26.33756 4i

To illustrate the procedure, high accuracy is waived: we take  $v_8 = 0$ , and  $a_0 = 2.821 - 6.565i$  in (2), thereby obtaining

$$\begin{aligned} v_4 &= 4.8i/(2.821 - 6.565i - 36) = -4.8i/(33.179 + 6.565i) \\ &= -(0.0276 + 0.139i). \end{aligned} \quad (3)$$

Applying (2) with  $r = 2$ , we have

$$\begin{aligned} v_2 &= 4.8i/[2.821 - 6.565i - 16 + 4.8i(0.0276 + 0.139i)] \\ &= -4.8i/(13.85 + 6.433i) \\ &= -(0.132 + 0.285i). \end{aligned} \quad (4)$$

Also

$$\begin{aligned} v_0 &= 2q/(a_0 - 4 - qv_2) \\ &= 9.6i/[2.821 - 6.565i - 4 + 4.8i(0.132 + 0.285i)] \\ &= -9.6i/(2.547 + 5.931i) \\ &= -(1.367 + 0.588i). \end{aligned} \quad (5) \quad (6)$$

We can now calculate the coefficients  $A_2, A_4, \dots$  in terms of  $A_0$ , but before doing so, we shall investigate the accuracy of the assumed value of  $a_0$ .

**3.44. Closer approximations to  $a_0$  and the  $v$ .** The first recurrence relation in (1) § 3.10 may be written

$$L = qv_0 - a_0 = 0. \quad (1)$$

Thus if  $a_0$  and  $v_0$  are calculated very accurately, the l.h.s. of (1) should be correspondingly small. Moreover, the magnitude of  $L$  will be an index of the error incurred due to the assumed value of  $a_0$  and in taking  $v_8 = 0$ . The numerical results in § 3.43 are not accurate enough to permit the calculation of  $L$ . However, we can show the method of obtaining a closer approximation to  $a_0$  and the  $v$  symbolically.

Since the  $v$  are functions of  $a_0$ , by (1) we have, with  $q$  constant,

$$L(a_0) = qv_0 - a_0. \quad (2)$$

Then if  $\delta a_0$  is small enough, by Taylor's theorem

$$L(a_0 + \delta a_0) \simeq L(a_0) + \delta a_0 \frac{\partial L(a_0)}{\partial a_0}. \quad (3)$$

We presume that  $L(a_0 + \delta a_0) \simeq 0$ , so we have Newton's well-known approximation

$$\delta a_0 = L(a_0) / \left[ -\frac{\partial L(a_0)}{\partial a_0} \right]. \quad (4)$$

Our next step is to derive an expression for  $-\partial L(a_0)/\partial a_0$  in terms of  $v_0, v_2, v_4, \dots$ . Then from (2)

$$-\frac{\partial L}{\partial a_0} = 1 - \frac{\partial(qv_0)}{\partial a_0}. \quad (5)$$

Also, by (2) § 3.11,  $v_0 = 2q/(a_0 - 4 - qv_2)$ , (6)

so  $\frac{\partial v_0}{\partial a_0} = \frac{-2q}{(a_0 - 4 - qv_2)^2} \frac{\partial}{\partial a_0} (a_0 - 4 - qv_2)$ , (7)

and, therefore,  $-\frac{\partial(qv_0)}{\partial a_0} = \frac{1}{2}v_0^2 \left[ 1 - \frac{\partial(qv_2)}{\partial a_0} \right]$ . (8)

Again, by (2) § 3.43,  $v_2 = q/(a_0 - 16 - qv_4)$ , (9)

so  $-\frac{\partial(qv_2)}{\partial a_0} = v_2^2 \left[ 1 - \frac{\partial(qv_4)}{\partial a_0} \right]$ . (10)

Substituting the r.h.s. of (10) into that of (8), yields

$$-\frac{\partial(qv_0)}{\partial a_0} = \frac{1}{2}v_0^2 \left[ 1 + v_2^2 \left( 1 - \frac{\partial(qv_4)}{\partial a_0} \right) \right]. \quad (11)$$

In general  $-\frac{\partial(qv_{2r-2})}{\partial a_0} = v_{2r-2}^2 \left[ 1 - \frac{\partial(qv_{2r})}{\partial a_0} \right], r > 1$  (12)

so by inserting the expression for  $-\partial(qv_4)/\partial a_0$  in (11), and repeating the process, we are led to

$$-\frac{\partial(qv_0)}{\partial a_0} = \frac{1}{2}v_0^2 [1 + v_2^2 + v_2^2 v_4^2 + v_2^2 v_4^2 v_6^2 + \dots]. \quad (13)$$

Accordingly, by (5), (13)

$$-\frac{\partial L}{\partial a_0} = 1 + \frac{1}{2}[v_0^2 + v_0^2 v_2^2 + v_0^2 v_2^2 v_4^2 + \dots] \quad (14)$$

$$= 1 + \frac{1}{2A_0^2}[A_2^2 + A_4^2 + A_6^2 + \dots]. \quad (15)$$

Hence

$$-2A_0^2 \frac{\partial L}{\partial a_0} = 2A_0^2 + \sum_{r=1}^{\infty} A_{2r}^2 = \frac{1}{\pi} \int_0^{2\pi} \text{ce}_{2n}^2(z, q) dz. \quad (16)^\dagger$$

We calculate  $L$  from (2) using adequately accurate values of  $v_0, a_0$ . Let the result be  $L = x_0 + iy_0$ . Now calculate  $-\partial L / \partial a_0$  from (14) using the  $v$ . Let  $-\partial L / \partial a_0 = x_1 + iy_1$ . Then from (4)

$$\delta a_0 \simeq (x_0 + iy_0) / (x_1 + iy_1) = x_2 + iy_2, \quad (17)$$

$$\text{so} \quad a_0 + \delta a_0 \simeq (2.82098 \ 8 + x_2) - (6.56490 \ 8 - y_2)i, \quad (18)$$

which is a closer approximation to the characteristic number than that in § 3.43. This new value of  $a_0$  is used to recalculate the  $v$ , as in § 3.43. The process may be repeated, but the number of decimal places required for increasing accuracy will increase at each repetition, owing to decrease in the real and imaginary parts of  $L$ .

**3.45. The series for  $\text{ce}_0(z, -4.8i)$ .** For this we use the  $v$  calculated in § 3.43. Then

$$A_2 = v_0 A_0, \quad A_4 = v_0 v_2 A_0, \quad A_6 = v_0 v_2 v_4 A_0,$$

and we find approximately that

$$\left. \begin{aligned} A_2 &= -(1.367 + 0.588i)A_0, \\ A_4 &= (0.013 + 0.468i)A_0, \\ A_6 &= (0.065 - 0.015i)A_0. \end{aligned} \right\} \quad (1)$$

Thus to a first approximation, we obtain

$$\begin{aligned} \text{ce}_0(z, 4.8i) &= A_0 [1 - (1.367 + 0.588i) \cos 2z + \\ &\quad + (0.013 + 0.468i) \cos 4z + (0.065 - 0.015i) \cos 6z + \dots]. \end{aligned} \quad (2)$$

Writing  $(\frac{1}{2}\pi - z)$  for  $z$  in (2) leads to

$$\begin{aligned} \text{ce}_0(z, -4.8i) &= A_0 [1 + (1.367 + 0.588i) \cos 2z + \\ &\quad + (0.013 + 0.468i) \cos 4z - (0.065 - 0.015i) \cos 6z + \dots]. \end{aligned} \quad (3)$$

It may be remarked that (3) is not (2) with the sign of  $i$  changed (see footnote to § 3.41).

**3.46.  $a_2$  and the  $A$  for  $\text{ce}_2(z, -4.8i)$ .** It is found by computation [57] that when  $s > 1.4688\dots$ ,  $a_0$  is complex, and its conjugate is  $a_2$ .<sup>‡</sup> By applying § 3.44 to the value of  $a_0$  in Table 4, we obtain

$$a_0 = 2.82120 \ 8 - 6.56266 \ 8i, \quad (1)$$

$$\text{so} \quad a_2 = 2.82120 \ 8 + 6.56266 \ 8i. \quad (2)$$

<sup>†</sup> This has not been equated to unity because  $q$  is imaginary (see § 2.21).

<sup>‡</sup> No formal proof of this has yet been published.

The  $v$  for  $ce_2$  are obtained from those for  $ce_0$  by merely altering the signs of the real parts—a procedure whose validity is easily established. Thus from (3), (4), (6) § 3.43, we get

$$\left. \begin{aligned} v_0 &= 1.367 - 0.588i, \\ v_2 &= 0.132 - 0.285i, \\ v_4 &= 0.0276 - 0.139i, \end{aligned} \right\} \quad (3)$$

these data being approximate for purposes of illustration. The  $A$  may be calculated from formulae at the beginning of § 3.45, but they can be found immediately by changing the signs of the real and imaginary parts in alternate  $A$  in (1) § 3.45. Thus for  $ce_2$  we have

$$\left. \begin{aligned} A_2 &= (1.367 - 0.588i)A_0, \\ A_4 &= (0.013 - 0.468i)A_0, \\ A_6 &= -(0.065 + 0.015i)A_0. \end{aligned} \right\} \quad (4)$$

Hence we find that

$$ce_2(z, 4.8i) = A_0[1 + (1.367 - 0.588i)\cos 2z + (0.013 - 0.468i)\cos 4z - (0.065 + 0.015i)\cos 6z + \dots], \quad (5)$$

and, therefore, writing  $(\frac{1}{2}\pi - z)$  for  $z$ ,

$$ce_2(z, -4.8i) = A_0[1 - (1.367 - 0.588i)\cos 2z + (0.013 - 0.468i)\cos 4z + (0.065 + 0.015i)\cos 6z + \dots]. \quad (6)$$

**3.47. Characteristic numbers for other functions when  $s$  is positive.** When  $s > s_0 > 0$  and the characteristic numbers are complex, numerical values indicate the following results [57]:

$$\begin{array}{lll} a_0 & \text{is conjugate to} & a_2, \\ a_1 & \text{,,} & \text{,,} \quad b_1, \\ a_3 & \text{,,} & \text{,,} \quad b_3, \\ b_2 & \text{,,} & \text{,,} \quad b_4. \end{array}$$

If  $s$  is large enough, numerical values indicate that [57]:

$$\begin{aligned} a_0 &\sim b_1, \\ a_3 &\sim b_4, \\ \frac{1}{2}(a_0 + b_1) &\sim \Gamma_0, \\ \frac{1}{2}(a_3 + b_4) &\sim \Gamma_1, \\ b_1 - a_0 &\sim \Delta_0, \\ b_4 - a_3 &\sim \Delta_1. \end{aligned}$$

See § 3.43 for meaning of symbols.

It may be remarked that when  $s$  varies from 0.16 to 1.44,  $a_0$  varies from 0.012836 to 1.689280, whilst  $a_2$  varies from 3.989297 to 2.481324. Thus the variation in  $(a_0 + a_2)$  is from 4.002132 to 4.170604, so  $(a_0 + a_2)$  is in the neighbourhood of 4 when  $s$  is in the range  $0.16 \leq s \leq 1.44$ , i.e. the two  $a$  are real. This is readily explained by aid of (1) § 3.41 and (1) § 3.42. From these formulae when  $s$  is moderate

$$(a_0 + a_2) = 4 + \left(\frac{1}{2} - \frac{5}{12}\right)s^2 + \left(\frac{7}{128} - \frac{763}{13824}\right)s^4 - \dots \quad (1)$$

$$= 4 + \frac{1}{12}s^2 - \frac{7}{13824}s^4 - \dots, \quad (2)$$

so the dominant term is 4. Numerical data show that as  $s \rightarrow +1.4688\dots$ ,  $a_0 \rightarrow (2-0)$ , and  $a_2 \rightarrow (2+0)$ .

Since the series for  $a_0$ ,  $a_2$  at (1) § 3.41, (1) § 3.42 proceed in powers of  $s^2$ , all the terms are real. The fact that  $a_0$ ,  $a_2$  are both complex when  $s > 1.4688\dots$  indicates, therefore, that the series cannot hold then, i.e. they appear to be divergent.

**3.50. cer, cei, ser, sei functions.** In § 3.40 et seq. we have seen that  $ce_m(z, -is)$  is a complex function of  $z$ , so we may put

$$ce_m(z, -is) = cer_m z + i cei_m z. \quad (1)$$

Writing the complex coefficients in polar form, we take

$$A_p^{(m)} = |A_p^{(m)}|e^{i\varphi_p}.$$

Thus, if  $ce_{2n}(z, +is) = \sum_{r=0}^{\infty} A_{2r}^{(2n)} \cos 2rz$ , by (2) § 2.18 we have

$$\begin{aligned} ce_{2n}(z, -is) &= (-1)^n \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} \cos 2rz \\ &= (-1)^n \sum_{r=0}^{\infty} (-1)^r |A_{2r}^{(2n)}| e^{i\varphi_{2r}} \cos 2rz \\ &= (-1)^n \left[ \sum_{r=0}^{\infty} (-1)^r |A_{2r}^{(2n)}| \cos \varphi_{2r} \cos 2rz + \right. \\ &\quad \left. + i \sum_{r=0}^{\infty} (-1)^r |A_{2r}^{(2n)}| \sin \varphi_{2r} \cos 2rz \right], \quad (2) \end{aligned}$$

so

$$\begin{aligned} cer_{2n} z &= (-1)^n \sum_{r=0}^{\infty} (-1)^r |A_{2r}^{(2n)}| \cos \varphi_{2r} \cos 2rz \\ &= (-1)^n |A_0^{(2n)}| \{1 - |v_0| \cos \varphi_2 \cos 2z + \\ &\quad + |v_0 v_2| \cos \varphi_4 \cos 4z - |v_0 v_2 v_4| \cos \varphi_6 \cos 6z + \dots\}, \quad (3) \end{aligned}$$

$$\begin{aligned} &= (-1)^n |A_0^{(2n)}| \{1 - |v_0| \cos \varphi_2 \cos 2z + \\ &\quad + |v_0 v_2| \cos \varphi_4 \cos 4z - |v_0 v_2 v_4| \cos \varphi_6 \cos 6z + \dots\}, \quad (4) \end{aligned}$$

and

$$\text{cei}_{2n} z = (-1)^n \sum_{r=0}^{\infty} (-1)^r |A_{2r}^{(2n)}| \sin \varphi_{2r} \cos 2rz \quad (6)$$

$$= (-1)^n |A_0^{(2n)}| \{1 - |v_0| \sin \varphi_2 \cos 2z + \\ + |v_0 v_2| \sin \varphi_4 \cos 4z - |v_0 v_2 v_4| \sin \varphi_6 \cos 6z + \dots\}. \quad (7)$$

These series are absolutely and uniformly convergent in any finite region of the  $z$ -plane. The series for  $\text{cer}_{2n+1}$ ,  $\text{cei}_{2n+1}$ ,  $\text{ser}_m$ ,  $\text{sei}_m$  may be found by procedure akin to that above. The modified functions  $\text{Cer}_m$ ,  $\text{Cei}_m$ , etc., are derived from the foregoing by writing  $iz$  for  $z$ .

**3.51. Bessel series for cer, cei, ser, sei.** Writing  $k = (is)^{\frac{1}{2}} = i^{\frac{1}{2}}l$  in (2) § 8.20, using the complex  $A$  from § 3.50, and the relation  $I_{2r}(u) = (-1)^r J_{2r}(iu)$ , we obtain

$$\text{ce}_{2n}(z, is) = \frac{\text{ce}_{2n}(0, is)}{A_0^{(2n)}} \sum_{r=0}^{\infty} A_{2r}^{(2n)} J_{2r}(2i^{\frac{1}{2}}l \sin z). \quad (1)$$

Writing  $(\frac{1}{2}\pi - z)$  for  $z$  gives

$$\text{ce}_{2n}(z, -is) = (-1)^n \frac{\text{ce}_{2n}(0, is)}{A_0^{(2n)}} \sum_{r=0}^{\infty} A_{2r}^{(2n)} J_{2r}(2i^{\frac{1}{2}}l \cos z). \quad (2)$$

By [202, pp. 121, 122], we have

$$J_{2r}(i^{\frac{1}{2}}lu) = \text{ber}_{2r} u + i \text{bei}_{2r} u = M_{2r}(u) e^{i\theta_{2r}(u)}. \quad (3)$$

Let  $\text{ce}_{2n}(0, is)/A_0 = E_{2n} e^{i\psi_{2n}}$ , and use (3) in (2); then we find that

$$\text{ce}_{2n}(z, -is) = (-1)^n E_{2n} \sum_{r=0}^{\infty} |A_{2r}^{(2n)}| M_{2r} e^{i(\theta_{2r} + \varphi_{2r} + \psi_{2n})}, \quad (4)$$

$$\text{so} \quad \text{cer}_{2n} z = (-1)^n E_{2n} \sum_{r=0}^{\infty} |A_{2r}^{(2n)}| M_{2r} \cos(\theta_{2r} + \varphi_{2r} + \psi_{2n}), \quad (5)$$

$$\text{and} \quad \text{cei}_{2n} z = (-1)^n E_{2n} \sum_{r=0}^{\infty} |A_{2r}^{(2n)}| M_{2r} \sin(\theta_{2r} + \varphi_{2r} + \psi_{2n}), \quad (6)$$

the argument of  $M$ ,  $\theta$  being  $2l \cos z$ . These series have the same convergence properties as in § 3.50. Series for the other functions may be derived in a similar way, while those for  $\text{Cer}_m$ , etc., may be obtained if  $iz$  be written for  $z$ .

By replacing  $k_1^2$  in (3) § 2, Appendix 1, with  $-ik_1^2$ , it will be found that when the fundamental ellipse tends to a circle,  $\text{Cer}$ ,  $\text{Cei}$ , etc., degenerate to constant multiples of the  $\text{ber}$  and  $\text{bei}$  functions.

## IV

### GENERAL THEORY: FUNCTIONS OF FRACTIONAL ORDER: SOLUTION OF EQUATIONS

**4.10. Introduction.** The discussion in this and in the next eight sections applies to any linear differential equation of the second order with single-valued periodic coefficients, e.g. (2), (5) Chapter I, these being Mathieu's and Hill's equations respectively.

Let  $y_1(z)$ ,  $y_2(z)$  be any two solutions which constitute a fundamental system. The complete solution is

$$y = Ay_1(z) + By_2(z), \quad (1)$$

$A$ ,  $B$  being arbitrary constants. If we write  $(z+\pi)$  for  $z$ , then  $y_1(z+\pi)$ ,  $y_2(z+\pi)$  are solutions also,  $\pi$  being the period of the coefficients. In accordance with the theory in [49], we have

$$y_1(z+\pi) = \alpha_1 y_1(z) + \alpha_2 y_2(z), \quad (2)$$

$$y_2(z+\pi) = \beta_1 y_1(z) + \beta_2 y_2(z), \quad (3)$$

where  $\alpha_1$ ,  $\alpha_2$ ,  $\beta_1$ ,  $\beta_2$  are constants determinable from the conditions at, say,  $z = 0$ . It is convenient in this discussion to choose the initial conditions  $y_1(0) = 1$ ,  $y_1'(0) = 0$ ,  $y_2(0) = 0$ ,  $y_2'(0) = 1$ . Substituting the first and third of these in (2), (3) yields

$$\alpha_1 = y_1(\pi), \quad \beta_1 = y_2(\pi). \quad (4)$$

Differentiating (2), (3) with respect to  $z$ , we get

$$y_1'(z+\pi) = \alpha_1 y_1'(z) + \alpha_2 y_2'(z), \quad (5)$$

and 
$$y_2'(z+\pi) = \beta_1 y_1'(z) + \beta_2 y_2'(z); \quad (6)$$

so insertion of the second and fourth conditions leads to

$$\alpha_2 = y_1'(\pi), \quad \beta_2 = y_2'(\pi). \quad (7)$$

If  $y_1$  were an even function of  $z$ , and  $y_2$  an odd one, on writing  $z = -\pi$  in (3) we should get

$$y_2(0) = 0 = \beta_1 y_1(\pi) - \beta_2 y_2(\pi) = \beta_1(\alpha_1 - \beta_2). \quad (8)$$

Since  $\beta_1 \neq 0$ , it follows that  $\alpha_1 = \beta_2$ , i.e.

$$y_1(\pi) = y_2'(\pi). \quad (9)$$

**4.11. Relationship between  $y(z)$  and  $y(z+\pi)$ .** From (1)–(3) § 4.10 we have

$$y(z+\pi) = Ay_1(z+\pi) + By_2(z+\pi) \quad (1)$$

$$\begin{aligned} &= A\{\alpha_1 y_1(z) + \alpha_2 y_2(z)\} + B\{\beta_1 y_1(z) + \beta_2 y_2(z)\} \\ &= (A\alpha_1 + B\beta_1)y_1(z) + (A\alpha_2 + B\beta_2)y_2(z). \end{aligned} \quad (2)$$

Thus, if  $\varphi$ , a constant, can be found such that  $(A\alpha_1 + B\beta_1) = \varphi A$ , and  $(A\alpha_2 + B\beta_2) = \varphi B$ , then by (1) § 4.10, (2) above may be written in the form

$$y(z+\pi) = \varphi y(z). \quad (3)$$

This necessitates

$$A(\alpha_1 - \varphi) + B\beta_1 = 0, \quad \text{or} \quad -A/B = \beta_1/(\alpha_1 - \varphi), \quad (4)$$

and  $A\alpha_2 + B(\beta_2 - \varphi) = 0, \quad \text{or} \quad -A/B = (\beta_2 - \varphi)/\alpha_2. \quad (5)$

Accordingly, if  $A, B$  are non-zero, we must have

$$(\alpha_1 - \varphi)(\beta_2 - \varphi) = \alpha_2 \beta_1, \quad (6)$$

or  $\varphi^2 - (\alpha_1 + \beta_2)\varphi + (\alpha_1 \beta_2 - \alpha_2 \beta_1) = 0. \quad (7)$

Since  $\alpha_1, \dots, \beta_2$  were determined in § 4.10, the two values of  $\varphi$  which satisfy (7) may be expressed in terms of  $y_1(\pi), y_1'(\pi), y_2(\pi), y_2'(\pi)$ .

**4.12. Introduction of the index  $\mu$ .** Let  $\varphi = e^{\mu\pi}$ , where  $\mu$  is a number dependent upon the parameters in the equation, i.e.  $a, q$  in (1) § 2.10. Also take  $\phi(z) = e^{-\mu z}y(z)$ , both of these being definitions. Writing  $(z+\pi)$  for  $z$  gives

$$\begin{aligned} \phi(z+\pi) &= e^{-\mu(z+\pi)}y(z+\pi) \\ &= e^{-\mu(z+\pi)}\varphi y(z), \end{aligned} \quad (1)$$

by (3) § 4.11,  $\phi(z+\pi) = e^{-\mu z}y(z) = \phi(z). \quad (2)$

Hence  $\phi(z)$  is periodic in  $z$  with period  $\pi$ . Since  $y(z)$  is a solution of the type of differential equation under consideration, it follows that  $e^{\mu z}\phi(z)$  is a solution.

**4.13. Complete solution of equation.** For our specific purpose we fix attention upon the equations

$$\frac{d^2 y}{dz^2} + (a - 2q \cos 2z)y = 0, \quad (1)$$

and  $\frac{d^2 y}{dz^2} + [a - 2q \psi(z)]y = 0. \quad (2)$

$\psi(z)$  is an even, differentiable† function of  $z$ , periodic therein with

† See footnote on p. 127.

period  $\pi$ , e.g.  $\psi(z) = \sum_{r=1}^{\infty} \theta_{2r} \cos 2rz$ .† By virtue of periodicity  $\pi$ , we take

$$\phi(z) = \sum_{r=-\infty}^{\infty} c_{2r} e^{2rzi}, \quad (3)$$

and

$$\phi(-z) = \sum_{r=-\infty}^{\infty} c_{2r} e^{-2rzi}. \quad (4)$$

Then by § 4.12, if  $\mu = \alpha + i\beta$ ,  $\alpha, \beta$  real,  $e^{\mu z}\phi(z)$  is a formal solution of (1) or of (2). Since both of these equations are unchanged,‡ if  $-z$  be written for  $z$ ,  $e^{-\mu z}\phi(-z)$  is an independent solution, provided either  $\alpha \neq 0$ , or when  $\alpha = 0$ ,  $\beta$  is non-integral. Hence the complete solutions of equations of type (1), (2) may be expressed in the form

$$y(z) = A e^{\mu z} \sum_{r=-\infty}^{\infty} c_{2r} e^{2rzi} + B e^{-\mu z} \sum_{r=-\infty}^{\infty} c_{2r} e^{-2rzi}, \quad (5)$$

$A, B$  being arbitrary constants. The above analysis is based on [215].

#### 4.14. Stability of solutions, $z$ real.

- (a) A solution is defined to be unstable if it tends to  $\pm\infty$  as  $z \rightarrow +\infty$ .
- (b) A solution is defined to be stable if it tends to zero or remains bounded as  $z \rightarrow +\infty$ .
- (c) A solution with period  $\pi$ ,  $2\pi$  is said to be neutral, but may be regarded as a special case of a stable solution.

Cases (a), (b) are non-periodic. § In (5) § 4.13, since the sigma terms are both periodic in  $z$ , the stability depends upon  $e^{\mu z}$ , i.e. upon  $\mu$ . It may, in general, have any real, imaginary, or complex value. If real and positive  $> 0$ ,  $e^{\mu z} \rightarrow +\infty$  with  $z$ . Hence the  $A$  member of (5) § 4.13 tends to  $\pm\infty$  as  $z \rightarrow +\infty$ , while the  $B$  member approaches zero. Thus the first part of the solution is unstable, but the second is stable, so the complete solution is unstable. If  $\mu$  is real and negative, instability arises from the  $B$  member.

When  $\mu = i\beta$ ,  $\beta$  non-integral (5) § 4.13 gives the stable solution

$$y(z) = A \sum_{r=-\infty}^{\infty} c_{2r} e^{(2r+\beta)zi} + B \sum_{r=-\infty}^{\infty} c_{2r} e^{-(2r+\beta)zi}. \quad (1)$$

If  $\beta$  is a rational fraction  $p/s$ ,  $p$  and  $s$  being prime to each other,

† In § 6.20 the  $\theta_{2r}$  must be such that  $\psi(z), \psi'(z), \dots$  are uniformly convergent and, therefore,  $\psi, \psi', \dots$  differentiable term by term. In a practical application the number of terms would usually be finite. It may sometimes be expedient for  $\psi(z)$  to have additional properties specified in § 6.10, with  $\omega = 1$ .

‡ With  $\psi$  as above.

§ Except as in (1) when the period is  $2s\pi$ .

the  $\Sigma$  members are both periodic, with period  $2s\pi$ . When  $\beta$  is irrational, the solution is oscillatory but bounded and non-periodic, i.e. it never repeats itself exactly at any interval. The  $\Sigma$  members in (1) are independent solutions of (1), (2) § 4.13.

If  $\mu = \alpha + i\beta$ , where  $\alpha, \beta$  are real and non-zero, (5) § 4.13 assumes the form

$$y(z) = Ae^{\alpha z} \sum_{r=-\infty}^{\infty} c_{2r} e^{(2r+\beta)zi} + Be^{-\alpha z} \sum_{r=-\infty}^{\infty} c_{2r} e^{-(2r+\beta)zi}, \quad (2)$$

and from what precedes, this is an unstable type. In numerical work it is possible, however, to arrange that  $\mu$  shall be either real or imaginary (according as the solution is unstable or stable), but not complex; also that  $0 < \beta < 1$  for convenience (see § 4.70).

### Recapitulation.

- (a) The solution is unstable if  $\mu$  is any real number  $\neq 0$ .
- (b) The solution is unstable if  $\mu = \alpha + i\beta$ ,  $|\alpha| > 0$ ,  $|\beta| > 0$ .
- (c) The solution is stable and periodic if  $\mu = i\beta$ ,  $\beta$  a rational fraction.
- (d) The solution is stable but non-periodic if  $\mu = i\beta$ ,  $\beta$  irrational.

In (a)–(d) the *complete* solution is implied.

**4.15. Alternative forms of solution.** In accordance with the theory of linear differential equations, we may choose as a first solution

$$y_1(z) = \frac{1}{2}A \left\{ e^{\mu z} \sum_{r=-\infty}^{\infty} c_{2r} e^{2rzi} + e^{-\mu z} \sum_{r=-\infty}^{\infty} c_{2r} e^{-2rzi} \right\} \quad (1)$$

$$\begin{aligned} &= \frac{1}{2}Ac_0(e^{\mu z} + e^{-\mu z}) + \frac{1}{2}Ae^{\mu z} \left\{ \sum_{r=1}^{\infty} (c_{2r} e^{2rzi} + c_{-2r} e^{-2rzi}) \right\} + \\ &\quad + \frac{1}{2}Ae^{-\mu z} \left\{ \sum_{r=1}^{\infty} (c_{2r} e^{-2rzi} + c_{-2r} e^{2rzi}) \right\} \quad (2) \end{aligned}$$

$$\begin{aligned} &= Ac_0 \cosh \mu z + A \sum_{r=1}^{\infty} \{ c_{2r} \cosh(\mu + 2ri)z + c_{-2r} \cosh(\mu - 2ri)z \} \\ &= A \sum_{r=-\infty}^{\infty} c_{2r} \cosh(\mu + 2ri)z. \quad (3) \end{aligned}$$

As in § 4.10 suppose  $y_1(0) = 1$ , then  $A = 1 / \sum_{r=-\infty}^{\infty} c_{2r}$  and, therefore,

$$\alpha_1 = y_1(\pi) = \cosh \mu \pi, \quad y_1(n\pi) = \cosh \mu n\pi, \quad (4)$$

for all finite values of  $\mu$ .

Starting with a negative sign within the r.h.s. of (1), we obtain a second independent solution, namely,

$$y_2(z) = B \sum_{r=-\infty}^{\infty} c_{2r} \sinh(\mu + 2ri)z. \quad (5)$$

As in § 4.10, let  $y'_2(0) = 1$ , then  $B = 1 / \sum_{r=-\infty}^{\infty} (\mu + 2ri)c_{2r}$ , so

$$\beta_2 = y'_2(\pi) = \cosh \mu\pi, \quad y'_2(n\pi) = \cosh \mu n\pi, \quad (6)$$

provided (5) is uniformly convergent for differentiation of the series to be permissible (see § 4.77).

From (4), (6) we get

$$y_1(\pi) = y'_2(\pi), \quad \text{or} \quad \alpha_1 = \beta_2, \quad (7)$$

$$\text{and} \quad y_1(n\pi) = y'_2(n\pi) = \cosh \mu n\pi. \quad (8)$$

Again, from (3)

$$y'_1(z) = A \sum_{r=-\infty}^{\infty} (\mu + 2ri)c_{2r} \sinh(\mu + 2ri)z,$$

provided (3) is uniformly convergent (see § 4.77). Then with  $z = \pi$ ,

$$\begin{aligned} \alpha_2 = y'_1(\pi) &= A \sinh \mu\pi \sum_{r=-\infty}^{\infty} (\mu + 2ri)c_{2r} \\ &= \frac{A}{B} \sinh \mu\pi. \end{aligned} \quad (9)$$

$$\text{Also} \quad y'_1(n\pi) = \frac{A}{B} \sinh \mu n\pi. \quad (10)$$

Writing  $z = \pi$  in (5) leads to

$$\beta_1 = y_2(\pi) = \frac{B}{A} \sinh \mu\pi. \quad (11)$$

$$\text{Also} \quad y_2(n\pi) = \frac{B}{A} \sinh \mu n\pi, \quad (12)$$

so

$$\alpha_2 \beta_1 = y'_1(\pi) y_2(\pi) = \sinh^2 \mu\pi, \quad y'_1(n\pi) y_2(n\pi) = \sinh^2 \mu n\pi. \quad (13)$$

From (4), (6)

$$\alpha_1 \beta_2 = y'_2(\pi) y_1(\pi) = \cosh^2 \mu\pi, \quad y'_2(n\pi) y_1(n\pi) = \cosh^2 \mu n\pi. \quad (14)$$

By (13), (14)

$$\alpha_1 \beta_2 - \alpha_2 \beta_1 = y'_2(\pi) y_1(\pi) - y'_1(\pi) y_2(\pi) = 1, \quad (15)^\dagger$$

$$\text{and} \quad y'_2(n\pi) y_1(n\pi) - y'_1(n\pi) y_2(n\pi) = 1. \quad (16)^\dagger$$

Substituting from (4), (6), (15) into (7) § 4.11, we find that

$$\varphi_1 = e^{\mu\pi}, \quad \varphi_2 = e^{-\mu\pi}, \quad \varphi_1 \varphi_2 = 1, \quad \varphi_1 = 1/\varphi_2.$$

† These are (2) § 2.191 with  $z = \pi$  and  $n\pi$ , respectively.

These results are valid for  $\mu = \alpha + i\beta$ ,  $\alpha \neq 0$ , or if  $\alpha = 0$ ,  $\beta$  is non-integral: also  $y_1(z)$  is even in  $z$ , whilst  $y_2(z)$  is odd therein. This restriction is removed in § 4.152.

**4.151. Extension of § 4.11.** Reverting now to (3) § 4.11, if  $y_1(z)$  be a solution of either (1), (2) § 4.13, then

$$y_1(z \pm \pi) = e^{\pm \mu \pi} y_1(z). \quad (1)$$

Also, if  $y_2(z)$  is a linearly independent solution,

$$y_2(z \pm \pi) = e^{\mp \mu \pi} y_2(z). \quad (2)$$

From (1) 
$$e^{\pm \mu \pi} = y_1(z \pm \pi)/y_1(z). \quad (3)$$

Hence 
$$\left. \begin{matrix} \cosh \\ \sinh \end{matrix} \right\} \mu \pi = [y_1(z + \pi) \pm y_1(z - \pi)]/2y_1(z). \quad (4)$$

If  $z = 0$ , and  $y_1(r\pi) \neq 0$ , (4) gives

$$\left. \begin{matrix} \cosh \\ \sinh \end{matrix} \right\} \mu \pi = [y_1(\pi) \pm y_1(-\pi)]/2y_1(0). \quad (5)$$

Similarly (2) yields the formulae

$$\left. \begin{matrix} \cosh \\ \sinh \end{matrix} \right\} \mu \pi = [y_2(z - \pi) \pm y_2(z + \pi)]/2y_2(z), \quad (6)$$

when  $z = \pi$ , 
$$= [y_2(0) \pm y_2(2\pi)]/2y_2(\pi), \quad (7)$$

provided  $y_2(0) \neq 0$ . Since  $\phi(z)$  has period  $\pi$ ,  $y_2(0) = 0$  entails  $y_2(n\pi) = 0$ , so (7) would then be indeterminate.

**4.152. A more general case.** From § 4.12 the solution of (1), (2) § 4.13 has the form

$$y = e^{\mu z} \phi(z), \quad (1)$$

where for convenience we shall take  $2\pi$  as the period of  $\phi(z)$ . Then  $\phi(-\pi) = \phi(\pi)$ , and

$$y(-\pi) = e^{-\mu \pi} \phi(\pi), \quad y(\pi) = e^{\mu \pi} \phi(\pi), \quad (2)$$

so 
$$y(\pi) - e^{2\mu \pi} y(-\pi) = 0. \quad (3)$$

Similarly we obtain

$$y'(\pi) - e^{2\mu \pi} y'(-\pi) = 0. \quad (4)$$

Let  $y_1(z)$  and  $y_2(z)$  be *any* two linearly independent solutions, and substitute  $y = Ay_1(z) + By_2(z)$  in (3), (4). Then we get

$$A[y_1(\pi) - e^{2\mu \pi} y_1(-\pi)] + B[y_2(\pi) - e^{2\mu \pi} y_2(-\pi)] = 0 \quad (5)$$

and 
$$A[y_1'(\pi) - e^{2\mu \pi} y_1'(-\pi)] + B[y_2'(\pi) - e^{2\mu \pi} y_2'(-\pi)] = 0. \quad (6)$$

For  $A, B$  non-zero, we must have

$$\begin{aligned} & [y_1(\pi) - e^{2\mu\pi}y_1(-\pi)][y'_2(\pi) - e^{2\mu\pi}y'_2(-\pi)] - \\ & - [y_2(\pi) - e^{2\mu\pi}y_2(-\pi)][y'_1(\pi) - e^{2\mu\pi}y'_1(-\pi)] = 0, \end{aligned} \quad (7)$$

$$\text{i.e.} \quad e^{4\mu\pi} - \frac{D}{c^2} e^{2\mu\pi} + 1 = 0, \quad (8)$$

where

$$D = y_1(-\pi)y'_2(\pi) + y_1(\pi)y'_2(-\pi) - y_2(-\pi)y'_1(\pi) - y_2(\pi)y'_1(-\pi),$$

and

$$y_1(\pi)y'_2(\pi) - y_2(\pi)y'_1(\pi) = y_1(-\pi)y'_2(-\pi) - y_2(-\pi)y'_1(-\pi) = c^2$$

(see § 2.191). Solving (8) leads to

$$\cosh 2\mu\pi = D/2c^2. \quad (9)$$

It may be remarked that conditions respecting oddness and evenness of the solutions have not been imposed. This is useful in connexion with problems like that in § 6.40 where the solutions are neither odd nor even. The preceding formulae are valid if  $n\pi$  is written for  $\pi$ ,  $n \geq 2$ .

If we assign the initial conditions

$$y_1(-\pi) = y'_2(-\pi) = 1, \quad y_2(-\pi) = y'_1(-\pi) = 0,$$

$$(9) \text{ becomes} \quad \cosh 2\mu\pi = [y_1(\pi) + y'_2(\pi)]/2, \quad (10)$$

and, as before,  $\pi$  may be replaced by  $n\pi$ .

**4.153. Functions having period  $2\pi$ .** Apart from § 4.152 the analysis in this chapter has been based upon a solution of the type  $e^{\mu z}\phi(z)$ , with  $\phi(z) = \sum_{r=-\infty}^{\infty} c_{2r} e^{2rz i}$ , which has period  $\pi$ . It is preferable that  $\mu$  should be real or imaginary ( $\mu = i\beta$ ,  $0 < \beta < 1$ ), but not complex. To obtain this objective when the parametric point  $(a, q)$  lies in certain regions of the  $(a, q)$ -plane (see Fig. 8), which are specified later in § 4.70, it is essential that  $\phi(z)$  has period  $2\pi$ . The results in §§ 4.10–4.151 are applicable if for  $\pi$  we write  $2\pi$ , and take

$$\phi(z) = \sum_{r=-\infty}^{\infty} c_{2r+1} e^{(2r+1)zi}; \quad (1)$$

also in all infinite series we change  $2r$  to  $(2r+1)$ . The relation corresponding to (4), (8) § 4.15 is now

$$y_1(n\pi) = y'_2(n\pi) = (-1)^n \cosh \mu n\pi. \quad (2)$$

**4.16. Form of solution when  $\mu = i\beta$ ,  $0 < \beta < 1$ .** In (3) § 4.15 write  $\mu = i\beta$ , and it becomes

$$y_1(z) = A \sum_{r=-\infty}^{\infty} c_{2r} \cos(2r+\beta)z, \quad (1)$$

while the same substitution in (5) § 4.15 gives the linearly independent solution

$$y_2(z) = B \sum_{r=-\infty}^{\infty} c_{2r} \sin(2r+\beta)z, \quad (2)$$

the  $i$  being dropped, since it is merely a constant multiplier. Hence the complete solution of

$$y'' + (a - 2q \cos 2z)y = 0, \quad (3)$$

takes the form

$$y(z) = A \sum_{r=-\infty}^{\infty} c_{2r} \cos(2r+\beta)z + B \sum_{r=-\infty}^{\infty} c_{2r} \sin(2r+\beta)z, \quad (4)$$

and this constitutes a fundamental system.

Corresponding to (4), (8), (13) § 4.15, we have

$$y_1(n\pi) = y'_2(n\pi) = \cos \beta n\pi \quad (5)$$

and

$$y'_1(n\pi)y_2(n\pi) = -\sin^2 \beta n\pi. \quad (6)$$

These are readily checked by using (1), (2) and the initial conditions  $y_1(0) = y'_2(0) = 1$ ,  $y_2(0) = y'_1(0) = 0$ .

*Additional forms of solution.* Replacing  $2r$  by  $(2r+1)$  in (1), (2), (4) in accordance with § 4.153, leads to the solutions (independent of each other)

$$y_1(z) = A \sum_{r=-\infty}^{\infty} c_{2r+1} \cos(2r+1+\beta)z, \quad (7)$$

and

$$y_2(z) = B \sum_{r=-\infty}^{\infty} c_{2r+1} \sin(2r+1+\beta)z, \quad (8)$$

giving for the complete solution

$$y(z) = A \sum_{r=-\infty}^{\infty} c_{2r+1} \cos(2r+1+\beta)z + B \sum_{r=-\infty}^{\infty} c_{2r+1} \sin(2r+1+\beta)z. \quad (9)$$

Corresponding to (2) § 4.153, we have

$$y_1(n\pi) = y'_2(n\pi) = (-1)^n \cos \beta n\pi, \quad (10)$$

which can be confirmed by using (7), (8).

It may be remarked that the  $A$ ,  $B$  are quite arbitrary, and need not have the values obtained in § 4.15, using the initial conditions stated there, i.e. any appropriate initial conditions may be chosen.

**4.17. Solution when  $\beta = 0$  or 1.** Consider any point  $(a, q)$ ,  $q > 0$ , in a stable region of Fig. 8A near  $a_{2n}$  but not upon it. Then (3) § 4.16 has two independent coexistent solutions, namely, (1), (2) § 4.16. On  $a_{2n}$ ,  $\beta = 0$  and (2) § 4.16 ceases to be a solution.† Substituting either (1) or (2) § 4.16 into (3) § 4.16 and equating the coefficient of  $\cos(2r+\beta)z$  or  $\sin(2r+\beta)z$  to zero for  $r = -\infty$  to  $\infty$ , we obtain the recurrence relation

$$[a - (2r + \beta)^2]c_{2r} - q(c_{2r+2} + c_{2r-2}) = 0. \quad (1)$$

With  $\beta = 0$ , (1) becomes

$$(a - 4r^2)c_{2r} - q(c_{2r+2} + c_{2r-2}) = 0. \quad (2)$$

Writing  $-r$  for  $r$  yields

$$(a - 4r^2)c_{-2r} - q(c_{-2r-2} + c_{-2r+2}) = 0. \quad (3)$$

Then (2), (3) are compatible provided  $c_0 \neq 0$  and  $c_{2r} = c_{-2r}$ ,  $r \geq 1$ . Hence, when  $\beta = 0$  and  $a = a_{2n}$ , (1) § 4.16 may be written

$$y_1(z) = A \left[ c_0 + 2 \sum_{r=1}^{\infty} c_{2r} \cos 2rz \right], \quad (4)$$

which is a constant multiple of  $ce_{2n}(z, q)$  as defined at (1) § 2.17.

When  $\beta = 1$ ,  $(a, q)$  is on  $b_{2n+1}$ , and (1) § 4.16 ceases to be a solution. The recurrence relation is now

$$[a - (2r + 1)^2]c_{2r} - q(c_{2r+2} + c_{2r-2}) = 0. \quad (5)$$

Writing  $-(r+1)$  for  $r$  in (5) gives

$$[a - (2r + 1)^2]c_{-2r-2} - q(c_{-2r} + c_{-2r-4}) = 0. \quad (6)$$

Then (5), (6) are compatible if  $c_{2r} = -c_{-2r-2}$ , e.g.  $c_0 = -c_{-2}$ ,  $c_2 = -c_{-4}$ . Hence (2) § 4.16 may be written

$$y_2(z) = 2B \sum_{r=0}^{\infty} c_{2r+1} \sin(2r+1)z, \quad (7)$$

where  $c_{2r+1}$  has been substituted for  $c_{2r}$ . This is a constant multiple of  $se_{2n+1}(z, q)$  defined at (3) § 2.17.

With  $\beta = 0$  in (7), (8) § 4.16,  $y_2(z)$  is not a solution since  $(a, q)$  is on  $a_{2n+1}$ . Then as above it can be shown that

$$y_1(z) = 2A \sum_{r=0}^{\infty} c_{2r+1} \cos(2r+1)z, \quad (8)$$

which is a constant multiple of  $ce_{2n+1}(z, q)$ . Similarly with  $\beta = 1$  in

† See § 2.13 et seq. The characteristic numbers for  $ce_m$ ,  $se_m$  are different.

(7), (8) § 4.16,  $y_1(z)$  ceases to be a solution, since  $(a, q)$  is on  $b_{2n+2}$ . Then we find that

$$y_2(z) = 2B \sum_{r=0}^{\infty} c_{2r+2} \sin(2r+2)z, \quad (9)$$

which is a constant multiple of  $\text{se}_{2n+2}(z, q)$ .

**4.18. Changing the sign of  $q$ .** Except in § 4.17, the sign of  $q$  has not been specified. Assuming, however, that the various solutions are for  $q > 0$ , those for the same  $a$  but  $q < 0$  may be derived if  $(\frac{1}{2}\pi - z)$  is written for  $z$ .

**4.19. General relationships between the solutions.** We commence with (2), (3) § 4.10, and use the values of  $\alpha_1, \alpha_2, \beta_1, \beta_2$  and the initial conditions stated therein. Then if  $y_1, y_2$  are independent solutions of (1) or of (2) § 4.13,

$$y_1(\pi+z) = y_1(\pi)y_1(z) + y_1'(\pi)y_2(z) \quad (1)$$

$$\text{and} \quad y_2(\pi+z) = y_2(\pi)y_1(z) + y_1(\pi)y_2(z). \quad (2)$$

Writing  $-z$  for  $z$ , and postulating that  $y_1$  is even and  $y_2$  odd in  $z$ , (1), (2) yield

$$y_1(\pi-z) = y_1(\pi)y_1(z) - y_1'(\pi)y_2(z) \quad (3)$$

$$\text{and} \quad y_2(\pi-z) = y_2(\pi)y_1(z) - y_1(\pi)y_2(z). \quad (4)$$

Formulae (2), (4) are analogous to those for the circular functions. Four additional relationships are obtained if (1)–(4) are differentiated with respect to  $z$ .

Writing  $(z-\pi)$  for  $z$  in (1), (2), and  $(\pi+z)$  for  $z$  in (3), (4) leads to

$$y_1(z) = y_1(\pi)y_1(\pi \mp z) - y_1'(\pi)y_2(\pi \mp z) \quad (5)$$

$$\text{and} \quad y_2(z) = \pm y_2(\pi)y_1(\pi \mp z) \mp y_1(\pi)y_2(\pi \mp z). \quad (6)$$

Differentiating (3), (4) with respect to  $z$  and using (2) § 2.191, we obtain

$$y_1'(\pi) = y_1(z)y_1'(\pi-z) + y_1'(z)y_1(\pi-z) \quad (7)$$

$$\text{and} \quad y_2(\pi) = y_2(z)y_2'(\pi-z) + y_2'(z)y_2(\pi-z). \quad (8)$$

The following may be derived from (1)–(4):

$$y_1(z)y_2(\pi-u) \pm y_2(z)y_1(\pi-u) = y_1(u)y_2(\pi \pm z) - y_2(u)y_1(\pi \pm z) \quad (9)$$

and

$$y_1(z)y_2(\pi+u) \pm y_2(z)y_1(\pi+u) = y_1(u)y_2(\pi \pm z) + y_2(u)y_1(\pi \pm z). \quad (10)$$

If  $y_1$  and/or  $y_2$  is periodic, the above relationships may be simplified. It may be remarked that if  $y_1$  is periodic in  $z$  with period  $\pi$  or  $2\pi$ ,

$y_2$  is non-periodic. But if  $y_1$  has period  $2s\pi$ ,  $s \geq 2$ ,  $y_2$  also has this period (see § 4.71).

**4.20. Determination of  $\mu$  when  $q$  is small.** Dividing (1)  $1^\circ$  § 4.750 by  $[(2r-i\mu)^2-a]$  and writing  $\xi_{2r} = q/[(2r-i\mu)^2-a]$  leads to

$$c_{2r} + \xi_{2r}(c_{2r+2} + c_{2r-2}) = 0. \quad (1)$$

With  $r = \dots -2, -1, 0, 1, 2, \dots$  we obtain the system of linear equations:

$$\left. \begin{array}{cccccccccccc} \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & 0 + \xi_{-4}c_{-6} + & c_{-4} & + \xi_{-4}c_{-2} + & 0 & + 0 & + 0 & + 0 & + & \cdot & & \\ \cdot & 0 + & 0 & + \xi_{-2}c_{-4} + & c_{-2} & + \xi_{-2}c_0 + & 0 & + 0 & + 0 & + & \cdot & \\ \cdot & 0 + & 0 & + 0 & + \xi_0c_{-2} + & c_0 & + \xi_0c_2 + & 0 & + 0 & + & \cdot & \\ \cdot & 0 + & 0 & + 0 & + 0 & + \xi_2c_0 + & c_2 & + \xi_2c_4 + & 0 & + & \cdot & \\ \cdot & 0 + & 0 & + 0 & + 0 & + 0 & + \xi_4c_2 + & c_4 & + \xi_4c_6 + & \cdot & & \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \end{array} \right\} = 0. \quad (2)$$

For (1)  $2^\circ$  § 4.70 to be a solution of Mathieu's equation, (2) must be a consistent system of equations, i.e. they must be satisfied simultaneously, so the eliminating determinant for the  $c$  (variables of the equations) must vanish. Thus we get the infinite determinant

$$\Delta(i\mu) = \begin{vmatrix} \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \xi_{-4} & 1 & \xi_{-4} & 0 & 0 & 0 & 0 & \cdot & \\ \cdot & 0 & \xi_{-2} & 1 & \xi_{-2} & 0 & 0 & 0 & \cdot & \\ \cdot & 0 & 0 & \xi_0 & \boxed{1} & \xi_0 & 0 & 0 & \cdot & \\ \cdot & 0 & 0 & 0 & \xi_2 & 1 & \xi_2 & 0 & \cdot & \\ \cdot & 0 & 0 & 0 & 0 & \xi_4 & 1 & \xi_4 & \cdot & \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \end{vmatrix} = 0. \quad (3)$$

When expanded this constitutes an equation for  $\mu$ . If in the  $\xi$  we write  $\mu = 0$ , the determinant  $\Delta(0)$  is obtained.

**4.21. Convergence of (3) § 4.20.** An infinite determinant is absolutely convergent if (a) the product of the diagonal elements is absolutely convergent, (b) the sum of the non-diagonal elements is absolutely convergent. (a) is satisfied, since the product is unity, while for (b) we have to demonstrate the convergence of

$$\sum_{r=-\infty}^{\infty} |1/[(2r-i\mu)^2-a]| = \frac{1}{4} \sum_{r=-\infty}^{\infty} \frac{1}{r^2} \left| 1 / \left[ \left(1 - \frac{i\mu}{2r}\right)^2 - \frac{a}{4r^2} \right] \right|. \quad (1)$$

When  $|r|$  is large enough, the terms under the sigma sign on the r.h.s. of (1) are each  $< |r|^{-p}$ ,  $1 < p < 2$ . Now the series  $\sum_1^{\infty} 1/r^p$  is known to converge, so (3) § 4.20 converges absolutely for all finite  $a$  and  $\mu$ , provided no denominator of one of the  $\xi_r$  vanishes, i.e.

$$(2r - i\mu) \neq \pm a^{\frac{1}{2}}.$$

#### 4.22. $\Delta(i\mu)$ as a function of the complex variable.

- (a) (i) Writing  $-\mu$  for  $\mu$  and  $-r$  for  $r$  leaves  $\Delta(i\mu)$  unaltered, since  $(2r - i\mu)^2 = (-2r + i\mu)^2$ .  
 (ii)  $r$  takes all integral values from  $-\infty$  to  $+\infty$ , so that transposition of the elements with  $+r$  and  $-r$  leaves  $\Delta(i\mu)$  unaltered. Hence  $\Delta(i\mu) = \Delta(-i\mu)$ , so that  $\Delta(i\mu)$  is an even function of  $\mu$ . Further, if  $a, q$  are real, so also is  $\Delta(i\mu)$ .  
 (b)  $[2r + i(\mu + 2i)]^2 = [2(r-1) + i\mu]^2$ , so replacing  $(r-1)$  by  $r$  in the second bracket gives  $(2r + i\mu)^2$ , the determinant is unchanged and  $\Delta(i\mu) = \Delta[i(\mu + 2i)]$ . Hence  $\Delta$  is periodic in  $\mu$  with period  $2i$ , so its behaviour everywhere is deducible from that in the infinite strip of the  $\mu$ -plane,  $0 \leq \text{Im}(\mu) \leq 1$ .  
 (c) The only singularities of  $\Delta$  are simple poles which occur when  $[(2r - i\mu)^2 - a] = 0$ , i.e.  $\mu = i(a^{\frac{1}{2}} - 2r)$  and  $-i(a^{\frac{1}{2}} + 2r)$ . Now the function  $\chi(i\mu) = 1/(\cos i\mu\pi - \cos \pi a^{\frac{1}{2}})$  has simple poles at these values of  $\mu$ ,† while its period is that of  $\Delta(i\mu)$ .  
 (d) From (c) it follows that the function

$$\psi(i\mu) = \Delta(i\mu) - C\chi(i\mu) \quad (1)$$

will have no singularities if  $C$  is suitably chosen, so by Liouville's theorem it must be a constant.

- (e) To determine  $C$  we proceed as follows: When  $\mu \rightarrow \infty$ , all the  $\xi$  in (3) § 4.20 tend to zero, and the diagonal elements alone remain. Thus  $\lim_{\mu \rightarrow \infty} \Delta(i\mu) = 1$ . Also  $\lim_{\mu \rightarrow \infty} \chi(i\mu) = 0$ , and, therefore,  $\psi(i\mu) = 1$ . Then

$$C\chi(i\mu) = \Delta(i\mu) - 1,$$

$$\text{or} \quad C = [\Delta(i\mu) - 1]/\chi(i\mu). \quad (2)$$

When  $\mu = 0$ ,  $\chi(0) = 1/(1 - \cos \pi a^{\frac{1}{2}})$ , while the value of (3) § 4.20 is  $\Delta(0)$ , the  $\xi_r$  being  $q/(4r^2 - a)$ ,  $a \neq 4r^2$ , to avoid an infinity. Hence by (2)

$$C = [\Delta(0) - 1][1 - \cos \pi a^{\frac{1}{2}}]. \quad (3)$$

† We assume that  $a \neq 4r^2$ , so  $\mu = 0$  is not a pole.

With this value of  $C$ , (1) is devoid of singularities in the  $\mu$ -plane. The preceding analysis is based upon [215].

**4.23. Solution of (3) § 4.20.** This determinantal equation is satisfied if  $\mu$  be such that  $\Delta(i\mu) = 0$ . Substituting this for  $\Delta$  in (2) § 4.22 and equating to (3) § 4.22, we have

$$1/\chi(i\mu) = [1 - \Delta(0)][1 - \cos \pi a^\dagger]. \quad (1)$$

Now  $1/\chi(i\mu) = \cos i\mu\pi - \cos \pi a^\dagger$ , so by (1) we get

$$\begin{aligned} \cos i\mu\pi &= \cos \pi a^\dagger + [1 - \Delta(0)][1 - \cos \pi a^\dagger] \\ &= 1 - \Delta(0)[1 - \cos \pi a^\dagger] \end{aligned} \quad (2)$$

$$\text{or} \quad \sin^2 \frac{1}{2}i\mu\pi = \Delta(0)\sin^2 \frac{1}{2}\pi a^\dagger \quad (a \neq 4r^2). \quad (3)$$

This result is obtained in [213] without recourse to the complex variable.

The values of  $\mu$  which satisfy (3) above, satisfy (3) § 4.20 also. Hence  $\mu$  is determined if  $\Delta(0)$  can be evaluated. If  $q$  is small,† by aid of [213] we find that

$$\Delta(0) \simeq 1 - \frac{\pi q^2 \cot \frac{1}{2}\pi a^\dagger}{4a^\dagger(a-1)}, \quad (4)$$

so (2) may be written

$$\cos i\mu\pi \simeq \cos \pi a^\dagger + [\pi q^2 \sin \pi a^\dagger / 4a^\dagger(a-1)] \quad (a \neq m^2). \quad (5)$$

**4.24. The roots of (3) § 4.20.** The determinant being an even function of  $i\mu$ , if  $i\mu_0$  is a root of  $\Delta(i\mu) = 0$ , so is  $-i\mu_0$ . Since a linear D.E. of the second order has no more than two independent solutions,  $\pm i\mu_0$  are the only *distinctive* roots. Now the non-diagonal elements are  $\xi_{2r} = q/[(2r - i\mu)^2 - a]$ , and if we write  $i\mu = (i\mu_0 - 2r)$  in the elements on either side of the origin where  $r = 0$ ,  $\xi_{2r}$  above is obtained. The result of treating all non-diagonal elements in this way is merely to shift the origin, and to leave  $\Delta(i\mu)$  unchanged. It follows that the roots are  $i\mu = \pm i\mu_0 - 2r$ ,  $r$  being any integer. If  $\mu_0$  is real, the roots occur in conjugate complex pairs  $i\mu_0 - 2r$ ,  $-i\mu_0 - 2r$ . If  $\mu_0$  is imaginary ( $= i\beta$ ), the roots occur in the real pairs  $\pm\beta - 2r$ . For  $\mu_0 = \alpha + i\beta$ ,  $i\mu_0 = i\alpha - \beta$ . Since  $r$  is any integer, we have the conjugate pair  $i\alpha - \beta - 2r$ , and  $-i\alpha + \beta - 2(r + \beta) = -i\alpha - \beta - 2r$ , provided  $\beta$  is an integer. Hence  $\mu$  may be complex if its imaginary part is integral.

† It suffices if the term in  $q^2$  in (4) is small compared with unity.

*Recapitulation.*

- (a) If  $\mu_0$  is real and  $r = 0$ ,  $\mu = \pm\mu_0$  is real.
- (b) If  $\mu_0$  is real and  $r \neq 0$ ,  $\mu$  is complex.
- (c) If  $\mu_0$  is imaginary,  $\mu$  is imaginary for all  $r$ .
- (d) If  $\mu_0 = \alpha + i\beta$ ,  $\beta$  an integer,  $\mu$  is complex for all  $r$ .

As shown in § 4.70 the form of solution may be chosen to make  $\mu$  either real or imaginary (according to the position of  $a$ ,  $q$  in the plane, Fig. 8), but not complex. These remarks apply to all real values of  $a$ ,  $q$  finite. The determinantal method of finding  $\mu$  is unsuitable for numerical evaluation unless  $q$  is small. When  $q$  exceeds, say,  $q_0$ , the methods exemplified in Chapter V should be used to get accurate results.

**4.30. Alternative form of general solution [186].** For the first solution we take

$$y_1(z) = e^{\mu z} \phi(z, \sigma), \quad (1)$$

$\phi$  being periodic in  $z$  with period  $\pi$  or  $2\pi$ , and  $\sigma$  a new parameter. When  $(a, q)$  lies between  $a_0$ ,  $b_2$  in Fig. 8, we shall obtain the form

$$\begin{aligned} \phi(z, \sigma) = \sin(z-\sigma) + s_3 \sin(3z-\sigma) + s_5 \sin(5z-\sigma) + \dots + \\ + c_3 \cos(3z-\sigma) + c_5 \cos(5z-\sigma) + \dots, \end{aligned} \quad (2)$$

$\sigma$  being dependent upon  $a$ ,  $q$ , as also are the  $c$ ,  $s$ .  $\phi$  has no term in  $\cos(z-\sigma)$  as its inclusion would introduce a *non-periodic* term, as shown below. For convenience the coefficient of  $\sin(z-\sigma)$  is taken as unity for all  $q$ . Since  $\sigma$ ,  $a$ ,  $q$  are interrelated, we assume that

$$a = 1 + qf_1(\sigma) + q^2f_2(\sigma) + q^3f_3(\sigma) + \dots; \quad (3)$$

$$\text{also} \quad \mu = qg_1(\sigma) + q^2g_2(\sigma) + q^3g_3(\sigma) + \dots, \quad (4)$$

there being no term devoid of  $q$ , and we take

$$\phi(z, \sigma) = \sin(z-\sigma) + qh_1(z, \sigma) + q^2h_2(z, \sigma) + q^3h_3(z, \sigma) + \dots, \quad (5)$$

where  $f$ ,  $g$  are functions of  $\sigma$ , the  $h$  being functions of  $z$ ,  $\sigma$ , *periodic* in  $z$ . Substituting the r.h.s. of (1) into  $y'' + (a - 2q \cos 2z)y = 0$  gives

$$e^{\mu z} [\phi'' + 2\mu\phi' + (\mu^2 + a - 2q \cos 2z)\phi] = 0,$$

and by the aid of (3)–(5) we get

$$e^{\mu z} \left\{ \begin{aligned} & -\sin(z-\sigma) + qh_1'' + q^2h_2'' + q^3h_3'' + \dots + \\ & + 2(qg_1 + q^2g_2 + q^3g_3 + \dots)[\cos(z-\sigma) + qh_1' + q^2h_2' + q^3h_3' + \dots] + \\ & + [(qg_1 + q^2g_2 + q^3g_3 + \dots)^2 + 1 + qf_1 + q^2f_2 + \dots - 2q \cos 2z] \times \\ & \quad \times [\sin(z-\sigma) + qh_1 + q^2h_2 + \dots] \end{aligned} \right\} = 0. \quad (6)$$

Taking

$$\begin{aligned} 2 \cos 2z \sin(z-\sigma) &= [\sin(3z-\sigma) - \sin(z+\sigma)] \\ &= [\sin(3z-\sigma) - \sin(z-\sigma)\cos 2\sigma - \cos(z-\sigma)\sin 2\sigma], \end{aligned}$$

and equating coefficients of  $q^0, q, q^2, \dots$  to zero we obtain

$$q^0: \quad -\sin(z-\sigma) + \sin(z-\sigma) = 0 \quad \text{identically}; \quad (7)$$

$$q: \quad h_1'' + h_1 + f_1 \sin(z-\sigma) + 2g_1 \cos(z-\sigma) - 2 \sin(z-\sigma) \cos 2z = 0.$$

Thus

$$\begin{aligned} h_1'' + h_1 + (2g_1 + \sin 2\sigma) \cos(z-\sigma) + \\ + (f_1 + \cos 2\sigma) \sin(z-\sigma) - \sin(3z-\sigma) = 0. \end{aligned} \quad (8)$$

Now the particular integrals corresponding to  $\cos(z-\sigma)$ ,  $\sin(z-\sigma)$  are  $\frac{1}{2}z \sin(z-\sigma)$  and  $-\frac{1}{2}z \cos(z-\sigma)$ . These are non-periodic and tend to  $\pm\infty$  as  $z \rightarrow +\infty$ . Since  $\phi$  is to be periodic, the coefficients of  $\cos(z-\sigma)$ ,  $\sin(z-\sigma)$  must be zero. Hence we must have  $g_1 = -\frac{1}{2} \sin 2\sigma$ ,  $f_1 = -\cos 2\sigma$ , leaving  $h_1'' + h_1 = \sin(3z-\sigma)$ , so

$$h_1 = -\frac{1}{8} \sin(3z-\sigma). \quad (9)$$

$$\begin{aligned} q^2: \quad h_2'' + h_2 + 2g_2 \cos(z-\sigma) - \frac{3}{4}g_1 \cos(3z-\sigma) + (g_1^2 + f_2) \sin(z-\sigma) + \\ + \frac{1}{8} \sin(3z-\sigma) \cos 2\sigma + \frac{1}{4} \sin(3z-\sigma) \cos 2z = 0, \end{aligned}$$

so

$$\begin{aligned} h_2'' + h_2 + 2g_2 \cos(z-\sigma) + \frac{3}{8} \cos(3z-\sigma) \sin 2\sigma + (\frac{1}{4} \sin^2 2\sigma + \frac{1}{8} + f_2) \sin(z-\sigma) + \\ + \frac{1}{8} \sin(3z-\sigma) \cos 2\sigma + \frac{1}{8} \sin(5z-\sigma) = 0. \end{aligned} \quad (10)$$

To avoid non-periodic terms we take  $g_2 = 0$ ,  $f_2 = -\frac{1}{4} + \frac{1}{8} \cos 4\sigma$ , leaving the equation

$$h_2'' + h_2 + \frac{3}{8} \cos(3z-\sigma) \sin 2\sigma + \frac{1}{8} \sin(3z-\sigma) \cos 2\sigma + \frac{1}{8} \sin(5z-\sigma) = 0,$$

of which the particular integral is

$$h_2 = [3 \sin 2\sigma \cos(3z-\sigma) + \cos 2\sigma \sin(3z-\sigma) + \frac{1}{8} \sin(5z-\sigma)]/64. \quad (11)$$

Proceeding in this way, on substituting for the various functions in (3), (4) we obtain

$$\begin{aligned} a = 1 - q \cos 2\sigma + \frac{1}{4} q^2 \left( -1 + \frac{1}{2} \cos 4\sigma \right) + \frac{1}{64} q^3 \cos 2\sigma + \\ + \frac{1}{16} q^4 \left( \frac{1}{3} - \frac{11}{32} \cos 4\sigma \right) - \frac{1}{32} q^5 \left( \frac{1}{9} \cos 2\sigma - \frac{13}{128} \cos 6\sigma \right) + \\ + \frac{1}{8192} q^6 \left( -\frac{893}{27} + \frac{9181}{216} \cos 4\sigma - \frac{35}{4} \cos 8\sigma \right) - \dots \end{aligned} \quad (12)$$

$$= 1 - q \cos 2\sigma - \mu^2 + q s_3. \quad (13)^\dagger$$

<sup>†</sup> This result was obtained by substituting (1) in the differential equation  $y'' + (a - 2q \cos 2z)y = 0$ , using  $\phi$  at (2), and equating to zero the coefficient of  $\sin(z-\sigma)$ .

$$\begin{aligned}\mu = & -\frac{1}{2}q \sin 2\sigma + \frac{3}{128}q^3 \sin 2\sigma - \frac{3}{1024}q^4 \sin 4\sigma - \\ & -\frac{1}{4096}q^5 \left( \frac{137}{9} \sin 2\sigma - \frac{9}{2} \sin 6\sigma \right) + \\ & + \frac{1}{16384}q^6 \left( \frac{337}{27} \sin 4\sigma - \frac{15}{4} \sin 8\sigma \right) + \dots \quad (14)\end{aligned}$$

$$= \frac{1}{2}q(-\sin 2\sigma + c_3). \quad (15)^\dagger$$

Also

$$\begin{aligned}s_3 = & -\frac{1}{8}q + \frac{1}{64}q^2 \cos 2\sigma - \frac{1}{512}q^3 \left( -\frac{14}{3} + 5 \cos 4\sigma \right) + \\ & + \frac{1}{4096}q^4 \left( -\frac{74}{9} \cos 2\sigma + 7 \cos 6\sigma \right) - \dots \quad (16)\end{aligned}$$

$$c_3 = \frac{3}{64}q^2 \sin 2\sigma - \frac{3}{512}q^3 \sin 4\sigma + \frac{1}{4096}q^4 \left( -\frac{274}{9} \sin 2\sigma + 9 \sin 6\sigma \right) - \dots \quad (17)$$

$$s_6 = \frac{1}{192}q^2 - \frac{1}{1152}q^3 \cos 2\sigma + \frac{1}{4096}q^4 \left( -\frac{155}{54} + \frac{82}{27} \cos 4\sigma \right) - \dots \quad (18)$$

$$c_6 = -\frac{7}{2304}q^3 \sin 2\sigma + \frac{11}{27648}q^4 \sin 4\sigma - \dots \quad (19)$$

$$s_7 = -\frac{1}{9216}q^3 + \frac{1}{49152}q^4 \cos 2\sigma - \dots \quad (20)$$

$$c_7 = \frac{35}{4 \cdot 42368}q^4 \sin 2\sigma - \dots \quad (21)$$

$$s_9 = \frac{1}{7 \cdot 37280}q^4 - \dots \quad (22)$$

. . . . .

It may be remarked that in (2) the coefficients of  $\cos(3z-\sigma)$ ,  $\cos(5z-\sigma)$ ,... are expressed in terms of  $\sin 2\sigma$ ,  $\sin 4\sigma$ ,..., while those of  $\sin(3z-\sigma)$ ,... are expressed in terms of  $\cos 2\sigma$ ,  $\cos 4\sigma$ ,...

If in (12) we write  $-\sigma$  for  $\sigma$ , it is unchanged because  $a$  is an even function of  $\sigma$ . Making this change in (14) alters the sign of  $\mu$ , since it is an odd function of  $\sigma$ . Thus referring to (1), we see that the

† This result was obtained by substituting (1) in the differential equation  $y'' + (a - 2q \cos 2z)y = 0$ , using  $\phi$  at (2), and equating to zero the coefficient of  $\cos(z - \sigma)$ .

second independent solution of Mathieu's equation may take the form

$$y_2 = e^{-\mu z} \phi(z, -\sigma). \quad (23)$$

$y_1, y_2$  constitute a fundamental system, and the complete solution, with two arbitrary constants, is [186]

$$y = Ae^{\mu z} \phi(z, \sigma) + Be^{-\mu z} \phi(z, -\sigma). \quad (24)$$

**4.31. Degeneration of (1) § 4.30 to  $ce_1(z, q)$  and  $se_1(z, q)$ .** When  $\sigma = -\frac{1}{2}\pi$ ,  $\mu = 0$ ,  $c_3 = c_5 = \dots = 0$ , and the series for  $a$  becomes that for  $a_1$  at (3) § 2.151. Also

$$s_3 = -\frac{1}{8}q - \frac{1}{64}q^2 - \frac{1}{1536}q^3 + \frac{11}{36864}q^4 - \dots, \quad (1)$$

and so on, while

$$\sin[(2n+1)z + \frac{1}{2}\pi] = \cos(2n+1)z. \quad (2)$$

Substituting in (1), (2) § 4.30, we obtain (16) § 2.13, the series for  $ce_1(z, q)$ . Similarly, when  $\sigma = 0$ , (1), (2) § 4.30 yield (2) § 2.14, the series for  $se_1(z, q)$ .

**4.32. Useful range of formulae in § 4.30.** The series for  $a, \mu$ , and the coefficients are similar in type to those in § 2.13 et seq. Such series probably diverge when  $q$ , real and positive, exceeds a certain value. The first term of (12) § 4.30 is unity, so if this series were used to compute  $a_5$  for  $ce_5(z, 0.4)$ , which exceeds 25,  $\cos 2\sigma$  would be correspondingly large, and low accuracy would ensue. This remark applies also to the series for  $\mu$  and the coefficients. Moreover, for computation the formulae in § 4.30 may be used when  $q$  is moderate and the point  $(a, q)$  lies between the characteristics for  $ce_0$  and  $se_2$  in Fig. 8.

If  $(a, q)$  were between the characteristics for  $se_2, ce_2$ , a more suitable form of solution would be obtained by taking

$$\begin{aligned} \phi(z, \sigma) = & \sin(2z - \sigma) + s_4 \sin(4z - \sigma) + s_6 \sin(6z - \sigma) + \dots + \\ & + c_4 \cos(4z - \sigma) + c_6 \cos(6z - \sigma) + \dots \end{aligned} \quad (1)$$

$$= \sin(2z - \sigma) + qh_1(z, \sigma) + q^2h_2(z, \sigma) + \dots, \quad (2)$$

there being no term in  $\cos(2z - \sigma)$ , to avoid a non-periodic term of the type  $z \sin(2z - \sigma)$  in the solution. If we assume that

$$a = 4 + qf_1(\sigma) + q^2f_2(\sigma) + \dots, \quad (3)$$

we find that  $f_1(\sigma) = 0$ , while

$$f_2(\sigma) = \frac{1}{8} - \frac{1}{4} \cos 2\sigma, \quad (4)$$

so

$$a = 4 + \frac{1}{2}q^2\left(\frac{1}{8} - \frac{1}{2} \cos 2\sigma\right) + \dots \quad (5)$$

Owing to the presence of 4 in (5), the coefficients of the terms in powers of  $q$  will be less than those in (12) § 4.30 if  $a$  is, say, 4.6.

In general the solution preferably has the forms at 1° (3), (6), 2° (2), (4) § 4.70, the corresponding series for  $a$  being of type (3) above, the leading term for  $ce_{2n}$ ,  $se_{2n}$  being  $4n^2$ , while that for  $ce_{2n+1}$ ,  $se_{2n+1}$  is  $(2n+1)^2$ .

**4.40. Maclaurin series solution.** If  $y$  is a solution of

$$y'' + (a - 2q \cos 2z)y = 0, \quad (1)$$

then by Maclaurin's theorem

$$y(z) = y(0) + zy'(0) + \frac{1}{2!}z^2y''(0) + \frac{1}{3!}z^3y'''(0) + \dots + \frac{1}{n!}z^ny^{(n)}(0) + R_n, \quad (2)$$

the derivatives being obtained by successive differentiation of (1) and insertion of  $z = 0$ . Although the procedure is simple, the solution so obtained has serious drawbacks:

1. The form, a power series in  $z$ , is markedly inferior in applications to those given previously. If (2) were periodic, its periodicity would be difficult to establish. Also it is unsuitable for interpreting the physical behaviour of a system, e.g. stability and instability.
2. If convergent, the rate of convergence is very slow and in many cases the number of terms needed to obtain accuracy for even moderate values of  $z$ , e.g.  $\frac{1}{2}\pi$ , would be prohibitive: see [12].
3. The convergence is difficult to establish.

**4.50. Relation between solutions in § 4.153 and § 4.30.** The respective forms are

$$\bar{y}_1(z) = e^{\mu z} \sum_{r=-\infty}^{\infty} \bar{c}_{2r+1} e^{(2r+1)zi} \quad (1)$$

and

$$y_1(z) = e^{\mu z} [\sin(z-\sigma) + s_3 \sin(3z-\sigma) + s_5 \sin(5z-\sigma) + \dots + c_3 \cos(3z-\sigma) + c_5 \cos(5z-\sigma) + \dots], \quad (2)$$

$\mu$  having the same value in both cases (see §4.70). Omitting the common factor  $e^{\mu z}$ , we expand the r.h.s. of (2) and obtain

$$\begin{aligned}\phi(z) &= \sin z \cos \sigma - \cos z \sin \sigma + s_3(\sin 3z \cos \sigma - \cos 3z \sin \sigma) + \\ &\quad + s_5(\sin 5z \cos \sigma - \cos 5z \sin \sigma) + \dots + c_3(\cos 3z \cos \sigma + \sin 3z \sin \sigma) + \\ &\quad + c_5(\cos 5z \cos \sigma + \sin 5z \sin \sigma) + \dots \quad (3)\end{aligned}$$

$$\begin{aligned}&= \cos \sigma(\sin z + s_3 \sin 3z + s_5 \sin 5z + \dots + c_3 \cos 3z + c_5 \cos 5z + \dots) - \\ &\quad - \sin \sigma(\cos z + s_3 \cos 3z + s_5 \cos 5z + \dots - c_3 \sin 3z - c_5 \sin 5z - \dots) \quad (4)\end{aligned}$$

$$= \sum_{r=0}^{\infty} [K_{2r+1} \cos(2r+1)z + L_{2r+1} \sin(2r+1)z], \quad (5)$$

where

$$\begin{aligned}K_{2r+1} &= (c_{2r+1} \cos \sigma - s_{2r+1} \sin \sigma) \quad (r > 0), & K_1 &= -\sin \sigma; \\ L_{2r+1} &= (s_{2r+1} \cos \sigma + c_{2r+1} \sin \sigma) \quad (r > 0), & L_1 &= \cos \sigma.\end{aligned}$$

Writing the circular functions in (5) in exponentials, we get

$$\phi(z) = \frac{1}{2} \sum_{r=0}^{\infty} [(K_{2r+1} - iL_{2r+1})e^{(2r+1)zi} + (K_{2r+1} + iL_{2r+1})e^{-(2r+1)zi}]. \quad (6)$$

Now

$$\sum_{r=-\infty}^{\infty} \bar{c}_{2r+1} e^{(2r+1)zi} = \sum_{r=0}^{\infty} [\bar{c}_{2r+1} e^{(2r+1)zi} + \bar{c}_{-2r-1} e^{-(2r+1)zi}]. \quad (7)$$

Hence by (6), (7) the two forms of solution are identical, provided

$$\bar{c}_{2r+1} = \frac{1}{2} \bar{Z}_0 (K_{2r+1} - iL_{2r+1}) \quad \text{and} \quad \bar{c}_{-2r-1} = \frac{1}{2} \bar{Z}_0 (K_{2r+1} + iL_{2r+1}), \quad (8)$$

$\bar{Z}_0$  being a constant. It follows from (8) that  $\bar{c}_{2r+1} \bar{Z}_0^{-1}$  and  $\bar{c}_{-2r-1} \bar{Z}_0^{-1}$  are conjugate complex numbers, while  $|c_{2r+1}| = |c_{-2r-1}|$ .† By adding the two parts of (8), we get

$$\bar{Z}_0 K_{2r+1} = \bar{c}_{2r+1} + \bar{c}_{-2r-1}, \quad (9)$$

and by subtracting, we have

$$\bar{Z}_0 L_{2r+1} = i(\bar{c}_{2r+1} - \bar{c}_{-2r-1}). \quad (10)$$

Writing  $r = 0$  in (9), (10), and substituting the values of  $K_1$ ,  $L_1$  from above, leads to

$$\bar{Z}_0 = -(\bar{c}_1 + \bar{c}_{-1})/\sin \sigma = i(\bar{c}_1 - \bar{c}_{-1})/\cos \sigma. \quad (11)$$

† Write

$$\bar{Z}_0 = M_0 e^{i\theta_0}, \quad \bar{c}_{2r+1} = \rho_{2r+1} e^{i\psi_{2r+1}},$$

$$\text{then } \bar{c}_{2r+1} \bar{Z}_0^{-1} = M_0^{-1} \rho_{2r+1} e^{i(\psi_{2r+1} - \theta_0)}, \quad \bar{c}_{-2r-1} \bar{Z}_0^{-1} = M_0^{-1} \rho_{2r+1} e^{i(\psi_{-2r-1} - \theta_0)}.$$

By virtue of the conjugate property

$$\psi_{2r+1} - \theta_0 = -(\psi_{-2r-1} - \theta_0) - 2s\pi,$$

so

$$\theta_0 = \frac{1}{2}(\psi_{2r+1} + \psi_{-2r-1}) + s\pi,$$

$s$  being integral.  $\bar{c}_{2r+1} \bar{Z}_0^{-1}$  and  $\bar{c}_{-2r-1} \bar{Z}_0^{-1}$  are complex conjugate only if  $\sigma$  is real, i.e. when  $(a, q)$  lies in an unstable region of Fig. 8.

By squaring and adding both sides of (9), (10) we obtain

$$\bar{Z}_0 = 2(\bar{c}_{2r+1} \bar{c}_{-2r-1})^\dagger / (K_{2r+1}^2 + L_{2r+1}^2)^\dagger, \quad (12)$$

and, with  $r = 0$ , 
$$\bar{Z}_0 = 2(\bar{c}_1 \bar{c}_{-1})^\dagger. \quad (13)$$

We have proved, therefore, that, save for a constant multiplier, the solutions in §§ 4.153, 4.30 are identical. A similar conclusion applies in connexion with the solution  $e^{\mu z} \sum_{r=-\infty}^{\infty} \bar{c}_{2r} e^{2rsi}$  and its alternative form. These results are to be expected, since the solution of Mathieu's equation must be unique.

**4.60. Division of the  $(a, q)$ -plane into stable and unstable regions.** Fig. 8 shows the 'charted' part of the plane, i.e. that portion for which the characteristic curves  $a_m$ ,  $b_m$  for the Mathieu functions of integral order have been computed. Consider the region in Fig. 8 B lying between  $a_1$  and  $b_2$ . On the curve  $a_1$ ,  $\sigma = -\frac{1}{2}\pi$  in (12) § 4.30. Now if  $\sigma = -\frac{1}{2}\pi + i\theta$ ,  $\cos 2\sigma = -\cosh 2\theta$ , whatever the sign of  $\theta$ , so if  $q > 0$  is fixed, (12) § 4.30 shows that  $a$  increases with increase in  $\theta$  until  $b_2$  is reached. On this curve from [191] we have

$$a = 4 + \frac{1}{2}q^2\left(\frac{1}{3} - \frac{1}{2}\cos 2\sigma\right) + \dots \quad (1)$$

with  $\sigma = 0$ . If in (1) we write  $\sigma = i\theta$ ,  $a$  decreases with increase in  $\theta$  until  $a_1$  is regained. Thus between  $a_1$ ,  $b_2$  with  $q > 0$ ,  $\sigma$  is complex or imaginary according as (12) § 4.30 or (1) is used. If we take  $\sigma = -\frac{1}{2}\pi + i\theta$ , then  $\sin 2\sigma = -i\sinh 2\theta$ , and (14) § 4.30 shows that  $\mu$  is imaginary and, therefore, by § 4.14 the solution is stable.

Starting from  $b_2$ , where  $\sigma = 0$  in (1), if for fixed  $q > 0$ ,  $\sigma$  (real) decreases, then  $a$  increases until  $a_2$  is reached where  $\sigma = -\frac{1}{2}\pi$ . Since  $\sigma$  is real in the intervening region, the series for  $\mu$  (like (14) § 4.30) may be shown to contain  $\sin 2\sigma$ ,  $\sin 4\sigma$ , etc. Thus  $\mu$  is real, and by § 4.14 an unstable solution is obtained for any  $(a, q)$  in the region.

Now consider the region between  $a_2$ ,  $b_3$  with fixed  $q > 0$ . On the former  $\sigma = -\frac{1}{2}\pi$  in (1), so the term in  $\cos 2\sigma$  is positive. If we take  $\sigma = (-\frac{1}{2}\pi + i\theta)$ , then  $\cos 2\sigma = -\cosh 2\theta$ , and by increasing  $\theta$  from zero in (1),  $b_3$  will ultimately be reached. Using the procedure suggested in § 4.32, we obtain [191]

$$a = 9 + \frac{1}{16}q^2 - \frac{1}{64}q^3 \cos 2\sigma + \dots \quad (2)$$

for the region in question, and on  $b_3$ ,  $\sigma = 0$ . Taking  $\sigma = i\theta$  in (2) and increasing  $\theta$  from zero,  $a_2$  will eventually be regained. Thus between  $a_2$ ,  $b_3$ ,  $\sigma$  is complex or imaginary according as (1) or (2) is

used. Since the series for  $\mu$  contains  $\sin 2\sigma$ ,  $\sin 4\sigma$ , etc.,  $\mu$  is imaginary in the region, so the solution of Mathieu's equation for an assigned  $(a, q)$  is stable.

In this way the  $(a, q)$ -plane, for  $q$  positive, may be divided into zones or regions in which the solution of Mathieu's equation corresponding to a point  $(a, q)$  is either stable or unstable. On the characteristic curves for the functions of integral order, the first solution is neutral, but the second solution treated in Chapter VII is unstable. When  $q$  is negative, by writing  $-q$  for  $q$  in the above series and using a similar argument, the plane may be divided up as illustrated in Figs. 8, 11. The series for the  $a$  hold if  $|q| < q_0$ , but the results may be established for the whole range of  $q$ .

*Summary.* (1) When  $(a, q)$ ,  $q > 0$  lies between  $a_m, b_{m+1}$  in Figs. 8, 11,  $\mu$  is imaginary, and the two solutions of Mathieu's equation are stable.

(2) When  $(a, q)$ ,  $q > 0$  lies between  $b_m, a_m$ ,  $\mu$  is real provided the appropriate form of solution is taken (see 2° § 4.70), and the complete solution of Mathieu's equation is unstable.

Apparatus for illustrating stability is described in [201] chap. XIV, also in § 15.40 et seq.

#### 4.70. Form of solution for different regions of $(a, q)$ -plane.

Certain advantages accrue by assuming different forms of solution corresponding to various regions in which the point  $(a, q)$  may lie in Figs. 8, 11. By adopting the convention given below,  $\mu$  will be either real as in 2°, or imaginary as in 1°, but never complex. It will then have the same value for the two forms of solution in 2° (real), and the three forms in 1° (imaginary).  $z$  is assumed to be real.

1°. *Stable solution,  $q$  small and positive.* When  $(a, q)$  lies between  $a_{2n}, b_{2n+1}$ , for the first solution we take

$$y_1(z) = e^{i\beta z} \sum_{r=-\infty}^{\infty} c_{2r} e^{2rzi} = e^{i\beta z} \phi(z)_{2r} \quad (1)$$

$$\text{or } y_1(z) = \sum_{r=-\infty}^{\infty} c_{2r} \cos(2r + \beta)z \quad (2)$$

$$\text{or } y_1(z) = e^{i\beta z} [\sin(2nz - \sigma) + s_2 \sin(2z - \sigma) + s_4 \sin(4z - \sigma) + \dots + c_2 \cos(2z - \sigma) + c_4 \cos(4z - \sigma) + \dots], \quad (3)$$

there being no term in  $\cos(2nz - \sigma)$ , e.g. if  $n = 1$ ,  $c_2 = 0$ , for the reason given in § 4.30. In these series  $\beta$  is real and  $0 < \beta < 1$ . If

$n \geq 1$ , formulae for  $a$ ,  $i\beta = \mu$ , and the coefficients  $c_{2r}$ ,  $s_{2r}$  may be developed as shown in § 4.30.

When  $(a, q)$  lies between  $a_{2n+1}$ ,  $b_{2n+2}$ , for the first solution we take

$$y_1(z) = e^{i\beta z} \sum_{r=-\infty}^{\infty} c_{2r+1} e^{(2r+1)zi} = e^{i\beta z} \phi(z)_{2r+1} \quad (4)$$

$$\text{or } y_1(z) = \sum_{r=-\infty}^{\infty} c_{2r+1} \cos(2r+1+\beta)z \quad (5)$$

$$\text{or } y_1(z) = e^{i\beta z} [\sin\{(2n+1)z-\sigma\} + s_1 \sin(z-\sigma) + s_3 \sin(3z-\sigma) + \dots + c_1 \cos(z-\sigma) + c_3 \cos(3z-\sigma) + \dots], \quad (6)$$

there being no term in  $\cos\{(2n+1)z-\sigma\}$ , e.g. if  $n = 1$ ,  $c_3 = 0$ , for the reason given in § 4.30. If  $n \geq 1$ , formulae for  $a$ ,  $i\beta = \mu$ , and the coefficients  $c_{2r+1}$ ,  $s_{2r+1}$  may be developed as shown in § 4.30.

The second solution is obtained by writing  $-z$  for  $z$  in (1), (4);  $\sin$  for  $\cos$  in (2), (5);  $-\beta$  for  $\beta$ ,  $-\sigma$  for  $\sigma$  in (3), (6). In each case the two solutions are linearly independent, provided  $\beta$  is in the range  $0 < \beta < 1$ , and constitute a fundamental system. When the initial conditions are specified, all forms of solution yield an identical result, since the solution is unique.

2°. *Unstable solution,  $q$  small and positive.* When  $(a, q)$  lies between  $b_{2n+2}$ ,  $a_{2n+2}$  for the first solution we take

$$y_1(z) = e^{\mu z} \sum_{r=-\infty}^{\infty} c_{2r} e^{2rzi} = e^{\mu z} \phi(z)_{2r} \quad (1)$$

$$\text{or } y_1(z) = e^{\mu z} [\sin(2nz-\sigma) + s_2 \sin(2z-\sigma) + s_4 \sin(4z-\sigma) + \dots + c_2 \cos(2z-\sigma) + c_4 \cos(4z-\sigma) + \dots], \quad (2)$$

where  $\mu$  (real)  $> 0$ . See remarks below (3) 1°.

When  $(a, q)$  lies between  $b_{2n+1}$ ,  $a_{2n+1}$ , for the first solution we take

$$y_1(z) = e^{\mu z} \sum_{r=-\infty}^{\infty} c_{2r+1} e^{(2r+1)zi} = e^{\mu z} \phi(z)_{2r+1} \quad (3)$$

$$\text{or } y_1(z) = e^{\mu z} [\sin\{(2n+1)z-\sigma\} + s_1 \sin(z-\sigma) + s_3 \sin(3z-\sigma) + \dots + c_1 \cos(z-\sigma) + c_3 \cos(3z-\sigma) + \dots]. \quad (4)$$

See remarks below (6) 1°.

The second solution is derived by making the substitutions stated in 1°. The period of  $\phi(z)_{2r}$  is  $\pi$ , while that of  $\phi(z)_{2r+1}$  is  $2\pi$ . Observe remark at end of 1°.

3°. *Stable solution,  $q$  moderate and positive.* See (1), (2), (4), (5) in 1°. The form at (3), (6) 1° is usually unsuitable for computation when  $q > 0.4$  approx.

4°. *Unstable solution,  $q$  moderate and positive.* As at (1), (3) in 2°.

5°. *Any solution,  $q$  negative.* In the solution for  $q > 0$ , write  $(\frac{1}{2}\pi - z)$  for  $z$ .

**4.71. Mathieu functions of real fractional order [134].** In § 4.16 (1), (2) represent coexistent solutions of Mathieu's equation, i.e. for an assigned value of  $q$  they have the same value of  $a$ . Consider the region in Fig. 11 between the curves  $a_m, b_{m+1}$  with  $m = 1$ . Take any line parallel to the  $a$ -axis and terminating on these curves. Hereon  $0 \leq \beta \leq 1$ . If for any assigned  $\beta$ , say 0.8, the  $a$  are calculated for  $q$  increasing from zero in small steps, and the points plotted, the characteristic curve  $\beta = 0.8$  is obtained. Lying between those for  $ce_1, se_2$ , we shall define it as that for the Mathieu function of real fractional order  $(1+\beta)$ . In general, if  $(a, q)$  lies between the curves  $a_m, b_{m+1}$ , the order of the function will be  $(m+\beta)$ , and the value of  $a$  on any curve is that for  $ce_{m+\beta}(z, q)$  and  $se_{m+\beta}(z, q)$ . Moreover, by computing a series of curves at intervals of, say,  $\beta = 0.1$ , we can plot an iso- $\beta$  chart,† of the type depicted in Fig. 11.

For  $q > 0$ ,  $0 < \beta < 1$ ,  $\beta$  real, we adopt the definitions [134]

$$\left. \begin{aligned} ce_{2n+\beta}(z, q) &= \sum_{r=-\infty}^{\infty} A_{2r}^{(2n+\beta)} \cos(2r+\beta)z, \\ se_{2n+\beta}(z, q) &= \sum_{r=-\infty}^{\infty} A_{2r}^{(2n+\beta)} \sin(2r+\beta)z, \end{aligned} \right\} \begin{array}{l} \text{coexistent solutions with} \\ a = a_{2n+\beta}; (a, q) \text{ between} \\ a_{2n} \text{ and } b_{2n+1}; \end{array} \quad (1) \quad (2)$$

$$ce_{2n+1+\beta}(z, q) = \sum_{r=-\infty}^{\infty} A_{2r+1}^{(2n+1+\beta)} \cos(2r+1+\beta)z, \quad \left. \begin{array}{l} \text{coexistent solutions} \\ \text{with } a = a_{2n+1+\beta}; \end{array} \right\} \quad (3)$$

$$se_{2n+1+\beta}(z, q) = \sum_{r=-\infty}^{\infty} A_{2r+1}^{(2n+1+\beta)} \sin(2r+1+\beta)z, \quad \left. \begin{array}{l} (a, q) \text{ between } a_{2n+1} \\ \text{and } b_{2n+2}. \end{array} \right\} \quad (4)$$

$q < 0$ . Writing  $(\frac{1}{2}\pi - z)$  for  $z$  in (1), (2), we obtain

$$\begin{aligned} ce_{2n+\beta}(\tfrac{1}{2}\pi - z, q) &= \cos \tfrac{1}{2}\beta\pi \sum_{r=-\infty}^{\infty} (-1)^r A_{2r}^{(2n+\beta)} \cos(2r+\beta)z + \\ &\quad + \sin \tfrac{1}{2}\beta\pi \sum_{r=-\infty}^{\infty} (-1)^r A_{2r}^{(2n+\beta)} \sin(2r+\beta)z, \end{aligned} \quad (5)$$

$$\begin{aligned} se_{2n+\beta}(\tfrac{1}{2}\pi - z, q) &= \sin \tfrac{1}{2}\beta\pi \sum_{r=-\infty}^{\infty} (-1)^r A_{2r}^{(2n+\beta)} \cos(2r+\beta)z - \\ &\quad - \cos \tfrac{1}{2}\beta\pi \sum_{r=-\infty}^{\infty} (-1)^r A_{2r}^{(2n+\beta)} \sin(2r+\beta)z. \end{aligned} \quad (6)$$

† Using an argument similar to that in § 3.25, it may be shown that the iso- $\beta$  curves are single-valued and continuous.

If we adopt the definitions

$$\left. \begin{aligned} \text{ce}_{2n+\beta}(z, -q) &= (-1)^n \sum_{r=-\infty}^{\infty} (-1)^r A_{2r}^{(2n+\beta)} \cos(2r+\beta)z, \\ \text{se}_{2n+\beta}(z, -q) &= (-1)^n \sum_{r=-\infty}^{\infty} (-1)^r A_{2r}^{(2n+\beta)} \sin(2r+\beta)z, \end{aligned} \right\} \begin{array}{l} \text{coexistent} \\ \text{solutions with} \\ a = a_{2n+\beta}, \end{array} \quad \begin{array}{l} (7) \\ (8) \end{array}$$

each function is a linearly independent solution of Mathieu's equation, and when  $q \rightarrow 0$  it degenerates to the appropriate form given in § 4.73. The functions corresponding to (3), (4) are obtained by writing  $(1+\beta)$  for  $\beta$  in (7), (8) and using  $A_{2r+1}^{(2n+1+\beta)}$  for  $A_{2r}^{(2n+\beta)}$ . If the tabular values of (1), (2) are known, those of (7), (8) may be calculated therefrom by aid of the following relationships derived from (5)–(8):

$$\begin{aligned} \text{ce}_{2n+\beta}(z, -q) \\ = (-1)^n [\cos \tfrac{1}{2}\beta\pi \text{ce}_{2n+\beta}(\tfrac{1}{2}\pi - z, q) + \sin \tfrac{1}{2}\beta\pi \text{se}_{2n+\beta}(\tfrac{1}{2}\pi - z, q)] \end{aligned} \quad (9)$$

and

$$\begin{aligned} \text{se}_{2n+\beta}(z, -q) \\ = (-1)^n [\sin \tfrac{1}{2}\beta\pi \text{ce}_{2n+\beta}(\tfrac{1}{2}\pi - z, q) - \cos \tfrac{1}{2}\beta\pi \text{se}_{2n+\beta}(\tfrac{1}{2}\pi - z, q)]. \end{aligned} \quad (10)$$

A similar remark applies concerning (3), (4).

The relationships for functions of order  $(2n+1+\beta)$  are derived from (9), (10) as described above with regard to (7), (8).

If the functions are defined as

$$\begin{aligned} \text{ce}_{2n+\beta}(z, +q) &= \sec \tfrac{1}{4}\beta\pi \sum_{r=-\infty}^{\infty} A_{2r}^{(2n+\beta)} \cos[(2r+\beta)z - \tfrac{1}{4}\beta\pi], \\ \text{se}_{2n+\beta}(z, +q) &= \sec \tfrac{1}{4}\beta\pi \sum_{r=-\infty}^{\infty} A_{2r}^{(2n+\beta)} \sin[(2r+\beta)z - \tfrac{1}{4}\beta\pi], \end{aligned} \quad (11)$$

then for  $q < 0$ , the substitution  $(\frac{1}{2}\pi - z)$  for  $z$  yields (11), but with  $(-1)^r$  within the sigma sign (see (7) and (8)). Although the functions defined thus are well suited for tabulation, since  $\text{ce}_{2n+\beta}(z, -q)$  is then equal to  $\text{ce}_{2n+\beta}(\frac{1}{2}\pi - z, q)$ , they have the following disadvantages: (a) they are neither odd nor even, (b) they do not reduce to  $\cos(m+\beta)z$ ,  $\sin(m+\beta)z$  when  $q \rightarrow 0$ , (c) they are more complicated than (1)–(4), (7), (8). These comments apply also to (5), (6).

As in § 3.21, all the above series may be proved absolutely and uniformly convergent in any real closed interval  $z_1 \leq z \leq z_2$ , or in any closed rectangle of the  $z$ -plane (see § 4.77).

For the pairs of functions (1), (7); (2), (8); etc. the iso- $\beta$  curves are symmetrical about the  $a$ -axis of Fig. 11. No two of these inter-

sect; for if they did, the equation would have more than two independent solutions corresponding to the point of intersection  $(a, q)$ , which is impossible. If  $\beta = p/s$ , a rational fraction less than unity,  $p, s$  being prime to each other, and  $z$  is real, the function has period  $2s\pi$ ,  $s \geq 2$ . When  $\beta$  is irrational, the function is not periodic, and tends neither to zero nor to infinity as  $z \rightarrow +\infty$ . By appropriate choice of  $(a, q)$  the function may have any real period  $2s\pi$ . An argument akin to that in § 3.25 may be used to show that the characteristic numbers and coefficients are continuous in  $q$ .†

*Modified functions of fractional order.* These are solutions of (1) §§ 2.30, 2.31, respectively, being defined as follows:

$$\frac{\text{Ce}}{\text{Se}_{m+\beta}}(z, \pm q) = -i \frac{\text{ce}}{\text{se}_{m+\beta}}(iz, \pm q) \quad (a_{m+\beta}). \quad (12)$$

The series representations may be derived from above by writing  $iz$  for  $z$ .

**4.711. Behaviour of the coefficients as  $\beta \rightarrow 0$  and 1.** Consider a point  $(a, q)$  in a stable region of Figs. 8 or 11 between  $a_{2n}$  and  $b_{2n+1}$ ; then  $0 < \beta < 1$ . With  $q > 0$  fixed, let  $a_{2n}$  be approached so that  $\beta \rightarrow 0$ . Then by § 4.17

$$\text{ce}_{2n+\beta}(z, q) \rightarrow \text{ce}_{2n}(z, q), \quad \text{se}_{2n+\beta}(z, q) \rightarrow 0; \quad (1)$$

so we must have

$$A_{-2r}^{(2n+\beta)} \rightarrow A_{2r}^{(2n+\beta)} \rightarrow \frac{1}{2} A_{2r}^{(2n)}, \quad A_0^{(2n+\beta)} \rightarrow A_0^{(2n)}; \quad a_{2n+\beta} \rightarrow a_{2n}. \quad (2)$$

Similarly, as  $\beta \rightarrow 1$ ,

$$\text{se}_{2n+\beta}(z, q) \rightarrow \text{se}_{2n+1}(z, q), \quad \text{ce}_{2n+\beta}(z, q) \rightarrow 0; \quad (3)$$

$$-A_{-2r-2}^{(2n+\beta)} \rightarrow A_{2r}^{(2n+\beta)} \rightarrow \frac{1}{2} B_{2r+1}^{(2n+1)}; \quad a_{2n+\beta} \rightarrow b_{2n+1}. \quad (4)$$

For  $(a, q)$  between  $a_{2n+1}$  and  $b_{2n+2}$ , as  $\beta \rightarrow 0$ ,

$$\text{ce}_{2n+1+\beta}(z, q) \rightarrow \text{ce}_{2n+1}(z, q), \quad \text{se}_{2n+1+\beta}(z, q) \rightarrow 0; \quad (5)$$

$$A_{-2r-1}^{(2n+1+\beta)} \rightarrow A_{2r+1}^{(2n+1+\beta)} \rightarrow \frac{1}{2} A_{2r+1}^{(2n+1)}; \quad a_{2n+1+\beta} \rightarrow a_{2n+1}. \quad (6)$$

As  $\beta \rightarrow 1$

$$\text{se}_{2n+1+\beta}(z, q) \rightarrow \text{se}_{2n+2}(z, q), \quad \text{ce}_{2n+1+\beta}(z, q) \rightarrow 0; \quad (7)$$

$$-A_{-2r-3}^{(2n+1+\beta)} \rightarrow A_{2r+1}^{(2n+1+\beta)} \rightarrow \frac{1}{2} B_{2r+2}^{(2n+2)}, \quad A_{-1} \rightarrow 0; \quad a_{2n+1+\beta} \rightarrow b_{2n+2}. \quad (8)$$

$r \geq 0$  except in (2), where  $r \geq 1$ .

† They are single-valued also.

#### 4.72. Normalization of $ce_{m+\beta}(z, q)$ , $se_{m+\beta}(z, q)$ .

1°.  $\beta = p/s$ , a rational fraction in its lowest terms. Since the functions have period  $2s\pi$ , we take

$$\frac{1}{s\pi} \int_0^{2s\pi} ce_{m+\beta}^2(z, q) dz = 1, \quad \frac{1}{s\pi} \int_0^{2s\pi} se_{m+\beta}^2(z, q) dz = 1. \quad (1)$$

Inserting the series (1)–(4) § 4.71 in these integrals leads to

$$\sum_{r=-\infty}^{\infty} [A_{2r}^{(2n+\beta)}]^2 = \sum_{r=-\infty}^{\infty} [A_{2r+1}^{(2n+1+\beta)}]^2 = 1. \quad (2)$$

2°.  $\beta$  an irrational number,  $0 < \beta < 1$ . If in (1),  $s \rightarrow +\infty$ , (2) follows, so we normalize accordingly.

Comparison of (1), (2) § 4.16 and (1), (2) § 4.71 shows that we may write  $A_{2r}^{(2n+\beta)} = Kc_{2r}$ , where  $K$  is a constant. Then from (2) we get

$$K^2 \sum_{r=-\infty}^{\infty} c_{2r}^2 = 1, \quad \text{so } K = 1 / \left[ \sum_{r=-\infty}^{\infty} c_{2r}^2 \right]^{\dagger}. \quad (3)^\dagger$$

If the  $c$  are found as in § 5.20 et seq.,  $K$  may be computed, e.g. § 5.311.

**4.73. Form of solution when  $q = 0$ .** At the intersection of an iso- $\beta$  curve with the  $a$ -axis in Fig. 11,  $q = 0$ . Then

$$a = m^2 + \Delta a = (m + \beta)^2,$$

$m$  being the order of the function whose characteristic curve intersects the  $a$ -axis at the point  $a = m^2$ . Thus the differential equation reduces to

$$y'' + (m + \beta)^2 y = 0, \quad (1)$$

whose formal solutions are  $\cos(m + \beta)z$ ,  $\sin(m + \beta)z$ .

By analysis akin to that in § 3.32 it can be shown that as  $q \rightarrow 0$ , all the  $A$  in (1), (2) § 4.71 except  $A_{2n}^{(2n+\beta)}$  tend to zero. By § 4.72  $A_{2n}^{(2n+\beta)} = 1$  when  $q = 0$ . A similar conclusion applies to (3), (4) § 4.71. Hence, when  $q = 0$ , the functions of fractional order become  $\cos(m + \beta)z$ ,  $\sin(m + \beta)z$ , so (1) is satisfied.

**4.74. Formula for  $\beta$  [134].** When the parametric point lies in a stable region of Figs. 8 or 11, formula (6) § 2.16 may be adapted to calculate  $\beta$ . When  $q > 0$ , if the curves bounding the region are  $a_m$  (lower),  $b_{m+1}$  (upper),  $m \geq 0$ , we take  $\nu = m + \beta$ . Then from (6) § 2.16

$$\begin{aligned} \nu^2 = a - \frac{1}{2(\nu^2 - 1)} q^2 - \frac{(5\nu^2 + 7)}{32(\nu^2 - 1)^3(\nu^2 - 4)} q^4 - \\ - \frac{9\nu^4 + 58\nu^2 + 29}{64(\nu^2 - 1)^5(\nu^2 - 4)(\nu^2 - 9)} q^6 + O(q^8). \end{aligned} \quad (1)$$

† This formula is valid when  $\beta$  is a rational fraction.

This formula is usable under the condition that  $|a| \gg |q^2/2(\nu^2-1)|$ , and that the ratio of each of the terms in  $q^{2r}$  to its predecessor is small. For a first approximation we have  $\nu^2 = a$ . Inserting this in the term in  $q^2$  and omitting the others, the second approximation is

$$\nu^2 = a - q^2/2(a-1). \quad (2)$$

Substituting from (2) into the second term on the r.h.s. of (1) and  $\nu^2 = a$  in the third and fourth, yields the third approximation, namely,

$$\begin{aligned} \nu^2 = a - \frac{(a-1)}{[2(a-1)^2 - q^2]} q^2 - \frac{(5a+7)}{32(a-1)^3(a-4)} q^4 - \\ - \frac{9a^2 + 58a + 29}{64(a-1)^5(a-4)(a-9)} q^6 + O(q^8). \end{aligned} \quad (3)$$

Since  $\nu^2 = (m+\beta)^2$ , we obtain (whatever the sign of  $q$ )

$$\begin{aligned} \beta \simeq \left[ a - \frac{(a-1)}{[2(a-1)^2 - q^2]} q^2 - \frac{(5a+7)}{32(a-1)^3(a-4)} q^4 - \right. \\ \left. - \frac{9a^2 + 58a + 29}{64(a-1)^5(a-4)(a-9)} q^6 \right]^{\frac{1}{2}} - m, \end{aligned} \quad (4)$$

provided no denominator vanishes. If  $\nu_1 = (m+\beta_1)$  calculated from (4) is fairly accurate, a closer result may be obtained by substituting  $\nu_1$  for  $\nu$  on the r.h.s. of (1), and recalculating  $\nu$ .

The accuracy obtained from (4) increases with decrease in  $q$ ,  $a$  being assigned. Broadly, for moderate accuracy we must have  $|a/q| \gg 1$ . Thus, if  $a$  is large enough,  $q$  also may be large, e.g. if  $a = 1000$ ,  $q$  might be 50. For lower accuracy the term in  $q^6$  may be omitted. When  $a$ ,  $q$  are such that adequate accuracy cannot be obtained with (4), the procedure described in §§ 5.11–5.14, 5.32 may be employed.

#### 4.750. Conjugate properties of the coefficients, $\mu$ real, $(a, q)$ in an unstable region.

1°. When  $(a, q)$  lies between  $b_{2n}$  and  $a_{2n}$ , the recurrence relation is

$$[a - (2r - i\mu)^2]c_{-2r} - q(c_{-2r+2} + c_{-2r-2}) = 0. \quad (1)$$

Writing  $-r$  for  $r$ , (1) becomes

$$[a - (2r + i\mu)^2]c_{-2r} - q(c_{-2r-2} + c_{-2r+2}) = 0. \quad (2)$$

Since  $a$ ,  $q$ ,  $\mu$  are real, it follows from (1), (2) that  $c_{2r}$  and  $c_{-2r}$  expressed in terms of  $c_0$  (real) are conjugate complex numbers.

2°. When  $(a, q)$  lies between  $b_{2n+1}$  and  $a_{2n+1}$ , the recurrence relation is

$$[a - (2r+1 - i\mu)^2]c_{2r+1} - q(c_{2r+3} + c_{2r-1}) = 0. \quad (1)$$

Writing  $-(r+1)$  for  $r$  in (1) gives

$$[a - (2r+1 + i\mu)^2]c_{-2r-1} - q(c_{-2r-3} + c_{-2r+1}) = 0. \quad (2)$$

Suppose that the  $c_{2r+1}$  are expressed in terms of  $c_1$ , and the  $c_{-2r-1}$  in terms of  $c_{-1}$ . Then  $c_{2r+1}$  and  $(c_1/c_{-1})c_{-2r-1}$ † are conjugate. In § 4.751 it is shown that  $|c_{2r+1}| = |c_{-2r-1}|$ , so  $|c_1| = |c_{-1}|$ .

The conjugate property of the coefficients is useful for checking purposes in numerical solutions. If this species of checking is waived, computation of  $c_{2r}$ ,  $r = 1, 2, \dots$ , in terms of  $c_0$ , and  $c_{2r+1}$ ,  $r = -1, 1, 2, \dots$ , in terms of  $c_1$  is sufficient.

#### 4.751. Alternative form of solution in unstable region.

1°. By 2° § 4.70, when  $(a, q)$  lies between  $b_{2n+1}$  and  $a_{2n+1}$ , the form of solution

$$y_1(z) = e^{\mu z} \sum_{r=-\infty}^{\infty} c_{2r+1} e^{(2r+1)zi} \quad (1)$$

ensures the reality of  $\mu$ . If  $\mu > 0$ ,  $y_1 \rightarrow 0$  as  $z \rightarrow -\infty$ . Since  $a, q$  are real, the  $c$  are complex. Then it may be shown that if  $z$  is real, save for a constant complex multiplier, say  $Z_0$ , there is a real solution which tends to zero as  $z \rightarrow -\infty$ .

$$\begin{aligned} \text{Let} \quad c_{2r+1} &= Z_0 d_{2r+1}, & Z_0 &= e^{i\theta_0}, & |Z_0| &= 1 \\ c_1 &= 1, & d_{2r+1} &= \rho_{2r+1} e^{i\phi_{2r+1}} \end{aligned} \quad (2)$$

for all  $r$ . We shall now demonstrate that  $d_{2r+1}$  and  $d_{-2r-1}$  are conjugate complex numbers. Substituting from (2) into (1) leads to

$$Z_0^{-1} y_1(z) = e^{\mu z} \sum_{r=-\infty}^{\infty} \rho_{2r+1} \{ \cos[(2r+1)z + \phi_{2r+1}] + i \sin[(2r+1)z + \phi_{2r+1}] \}. \quad (3)$$

For a real solution, the imaginary part of the r.h.s. of (3) must vanish identically. Hence

$$\rho_{2r+1} \sin[(2r+1)z + \phi_{2r+1}] - \rho_{-2r-1} \sin[(2r+1)z - \phi_{-2r-1}] \equiv 0, \quad (4)$$

and, therefore,

$$\rho_{2r+1} = \rho_{-2r-1}, \quad \text{and} \quad \phi_{2r+1} = -(\phi_{-2r-1} + 2s\pi), \quad (5)$$

$s$  being an integer. It follows that  $d_{2r+1}$  and  $d_{-2r-1}$  are conjugate, so (3) may be written

$$y_1(z) = 2Z_0 e^{\mu z} \sum_{r=0}^{\infty} \rho_{2r+1} \cos[(2r+1)z + \phi_{2r+1}]. \quad (6)$$

† By aid of 1°, 4.751, it may be shown that  $(c_1/c_{-1}) = e^{-2i\theta_0}$ .

The second independent solution is

$$y_2(z) = y_1(-z) = 2Z_0 e^{-\mu z} \sum_{r=0}^{\infty} \rho_{2r+1} \cos[(2r+1)z - \phi_{2r+1}]. \quad (7)$$

Then (6)  $\rightarrow 0$  as  $z \rightarrow -\infty$  if  $\mu > 0$ , while (7)  $\rightarrow \pm\infty$  as  $z \rightarrow -\infty$ .

*Determination of  $Z_0$ .* For all integral values of  $r$

$$c_{2r+1} = Z_0 d_{2r+1}, \quad \text{with } |Z_0| = 1. \quad (8)$$

Since  $d_{2r+1}$  and  $d_{-2r-1}$  are conjugate, it follows that

$$|c_{2r+1}| = |c_{-2r-1}|. \quad (9)$$

Thus we may write  $c_{2r+1} = \rho_{2r+1} e^{i\psi_{2r+1}}$ ,  $c_{-2r-1} = \rho_{2r+1} e^{i\psi_{-2r-1}}$ . Then

$$Z_0 = e^{i\theta_0} = c_{2r+1}/d_{2r+1} = e^{i(\psi_{2r+1} - \phi_{2r+1})} \quad (10)$$

$$= c_{-2r-1}/d_{-2r-1} = e^{i(\psi_{-2r-1} + \phi_{2r+1} + 2s\pi)}, \quad (11)$$

by (5). Hence

$$2\theta_0 = (\psi_{2r+1} - \phi_{2r+1}) + (\psi_{-2r-1} + \phi_{2r+1} + 2s\pi),$$

so

$$\theta_0 = \frac{1}{2}(\psi_{2r+1} + \psi_{-2r-1}) + s\pi. \quad (12)$$

It follows from the footnote in § 4.50 that  $\bar{Z}_0 = M_0 Z_0$ , i.e.  $\bar{Z}_0$  and  $Z_0$  have equal angles.

2°. When  $(a, q)$  lies between  $b_{2n}$ ,  $a_{2n}$ , by 2° § 4.70  $\mu$  is real if

$$y_1(z) = e^{\mu z} \sum_{r=-\infty}^{\infty} c_{2r} e^{2rz i}. \quad (1)$$

Take  $c_{2r} = \rho_{2r} e^{i\phi_{2r}}$ ,  $c_0 = 2\rho_0$  real, then for a real solution it may be shown that  $\rho_{2r} = \rho_{-2r}$ ,  $\phi_{2r} = -(\phi_{-2r} + 2s\pi)$ , so if  $r \geq 1$ ,  $c_{2r}$  and  $c_{-2r}$  are conjugate. Also

$$y_1(z) = 2e^{\mu z} \left\{ \rho_0 + \sum_{r=1}^{\infty} \rho_{2r} \cos(2rz + \phi_{2r}) \right\}, \quad (2)$$

$$\text{and } y_2(z) = y_1(-z) = 2e^{-\mu z} \left\{ \rho_0 + \sum_{r=1}^{\infty} \rho_{2r} \cos(2rz - \phi_{2r}) \right\}. \quad (3)$$

In this case  $Z_0 = 1$ .

**4.752. Example illustrating analysis in § 4.751.** We shall consider the solution of

$$y'' + (1 - 0.32 \cos 2z)y = 0, \quad (1)$$

obtained in § 5.33. The parametric point  $a = 1$ ,  $q = 0.16$ , lies in an unstable region between  $b_1$  and  $a_1$ . From 2° § 5.33 we have

$$\left. \begin{aligned} c_1 &= 1, \\ c_{-1} &= (5.95 \times 10^{-2} + 0.998i); \\ c_3 &= -(1.994 \times 10^{-2} + 1.198 \times 10^{-3}i), \\ c_{-3} &= -(2.38 \times 10^{-3} + 1.978 \times 10^{-2}i); \\ c_5 &= (1.325 \times 10^{-4} + 1.24 \times 10^{-5}i), \\ c_{-5} &= (2.024 \times 10^{-5} + 1.313 \times 10^{-4}i). \end{aligned} \right\} \quad (2)$$

1°. We find that  $|c_1| \simeq |c_{-1}|$ ,  $|c_3| \simeq |c_{-3}|$ ,  $|c_5| \simeq |c_{-5}|$ .

2°. (a)  $\psi_1 = 0$ ,  $\psi_{-1} = \tan^{-1}(0.998/0.0595) = 86.56^\circ$ .

Hence by (12), 1° § 4.751 with  $s = 0$ ,

$$\theta_0 = \frac{1}{2}(\psi_1 + \psi_{-1}) = 43.28^\circ. \quad (1)$$

(b)  $\psi_3 = \tan^{-1}(-1.198/-19.94) = 183.44^\circ$ ,

$$\psi_{-3} = \tan^{-1}(-1.978/-0.238) = 263.12^\circ.$$

Hence by (12), 1° § 4.751 with  $s = -1$ ,

$$\theta_0 = \frac{1}{2}(\psi_3 + \psi_{-3}) - 180^\circ = 43.28^\circ. \quad (2)$$

(c)  $\psi_5 = \tan^{-1}(0.124/1.325) = 5.37^\circ$ ,

$$\psi_{-5} = \tan^{-1}(1.313/0.2024) = 81.25^\circ.$$

Hence by (12), 1° § 4.751 with  $s = 0$ ,

$$\theta_0 = \frac{1}{2}(\psi_5 + \psi_{-5}) = 43.31^\circ. \quad (3)$$

The agreement at (1), (2), (3) is satisfactory for the purpose of illustration.

$$3^\circ. \quad Z_0 = e^{43.28^\circ i} = 0.728 + 0.686i$$

and

$$|Z_0| = 1.$$

$$4^\circ. \quad \left. \begin{aligned} d_1 &= c_1 e^{-43.28^\circ i} = e^{-43.28^\circ i} \\ d_{-1} &= c_{-1} e^{-43.28^\circ i} = e^{43.28^\circ i} \end{aligned} \right\} \text{conjugate.} \quad (1)$$

$$\left. \begin{aligned} d_3 &= c_3 e^{-43.28^\circ i} = |c_3| e^{140.16^\circ i} \\ d_{-3} &= c_{-3} e^{-43.28^\circ i} = |c_3| e^{219.84^\circ i} \end{aligned} \right\} \text{conjugate.} \quad (2)$$

$$\left. \begin{aligned} d_5 &= c_5 e^{-43.28^\circ i} = |c_5| e^{-37.91^\circ i} \\ d_{-5} &= c_{-5} e^{-43.28^\circ i} = |c_5| e^{37.97^\circ i} \end{aligned} \right\} \text{conjugate.} \quad (3)$$

As an exercise, the reader may check the remark in § 4.750 that  $c_{2r+1}$  and  $(c_1/c_{-1})c_{-2r-1}$  are conjugate.

$$5^\circ. \quad \left. \begin{aligned} \rho_1 &= 1, & \phi_1 &= -43.28^\circ; \\ \rho_3 &= 2 \times 10^{-2}, & \phi_3 &= 140.16^\circ; \\ \rho_5 &= 1.33 \times 10^{-4}, & \phi_5 &= -37.91^\circ. \end{aligned} \right\} \quad (1)$$

By 1° § 5.33  $\mu = 0.08$ .

6°. Two approximate independent solutions of (1) § 4.752 are

$$y_1(z) \simeq 2Z_0 e^{\mu z} \left\{ \sum_{r=0}^2 \rho_{2r+1} \cos[(2r+1)z + \phi_{2r+1}] \right\} \quad (1)$$

and

$$y_2(z) = y_1(-z) \simeq 2Z_0 e^{-\mu z} \left\{ \sum_{r=0}^2 \rho_{2r+1} \cos[(2r+1)z - \phi_{2r+1}] \right\}. \quad (2)$$

By combining these linearly independent solutions, we obtain the *even* solution

$$\frac{1}{4Z_0}(y_1 + y_2) = \bar{y}_1 \simeq \cosh \mu z \sum_{r=0}^2 \rho_{2r+1} \cos(2r+1)z \cos \phi_{2r+1} - \sinh \mu z \sum_{r=0}^2 \rho_{2r+1} \sin(2r+1)z \sin \phi_{2r+1}, \quad (3)$$

and the *odd* solution

$$\frac{1}{4Z_0}(y_1 - y_2) = \bar{y}_2 \simeq \sinh \mu z \sum_{r=0}^2 \rho_{2r+1} \cos(2r+1)z \cos \phi_{2r+1} - \cosh \mu z \sum_{r=0}^2 \rho_{2r+1} \sin(2r+1)z \sin \phi_{2r+1}. \quad (4)$$

In practical applications (3), (4) have the disadvantage that *both* tend to infinity with  $z$ .

**4.753. Formula for  $\mu$  when  $a < 0$ .**  $\mu$  may be calculated for  $(a, q)$  below  $a_0$  in Figs. 8, 11, by means of (4) § 4.74 with  $m = 0$ . Then  $\mu = -i\beta$ . The remarks on accuracy in the last paragraph of § 4.74 apply here also. As shown later, (7) § 4.91 may be used when  $(a, q)$  lies in an unstable region between  $b_m$  and  $a_m$ ,  $m > 0$ .

**4.760. The iso- $\mu$  curves in Fig. 11.** Consider the segment of any line between the curves  $b_m$ ,  $a_m$ , parallel to the  $a$ -axis, i.e. in an unstable region. The convention of § 4.70 ensures the reality of  $\mu$ . On  $b_m$  and  $a_m$ ,  $\mu = 0$ , while at some point on the segment of the line,  $\mu$  attains a maximum value. This is true also for points on the segment of a line parallel to the  $q$ -axis and terminating on  $a_m$ . Thus if the turning-point (nearest the  $a$ -axis) on an iso- $\mu$  curve is  $q = q_0$ , there are two values of  $a$  for any  $q > q_0$  on the curve. Moreover, the coefficients in the solutions corresponding to the two  $a$  are different, except at the turning-point. No two iso- $\mu$  curves intersect for the reason stated in § 4.71 regarding the same property of iso- $\beta$  curves. The iso- $\mu$  curves are asymptotic to the characteristic curves  $b_m$ ,  $a_m$  which bound the unstable region where they lie, and they have no linear asymptotes.

If the numerical data were available, families of iso- $\mu$  curves akin to those depicted in Fig. 11 could be plotted. Tabulation of  $a$ ,  $a^\dagger$ ,  $q$ ,  $\mu$  would permit the value of the latter being found immediately, or by interpolation. The solution of an equation with  $(a, q)$  in a 'charted' unstable region would then be completed by computing the coefficients in (1) or (3), 2° § 4.70, using the procedure in 2° § 5.33 and § 5.34.

**4.761. Functions of order  $m+\mu$ ,  $q$  positive.** When  $(a, q)$  lies in an unstable region between  $b_{2n}$  and  $a_{2n}$ , we define the functions of order  $(2n+\mu)$  by aid of (2), (3), 2° § 4.751. Thus

$$\text{ceu}_{2n+\mu}(\pm z, q) = K e^{\pm \mu z} \left\{ \rho_0 + \sum_{r=1}^{\infty} \rho_{2r} \cos(2rz \pm \phi_{2r}) \right\} \quad (b_{2n+\mu}). \quad (1, 2)$$

For the region between  $b_{2n+1}$ ,  $a_{2n+1}$  we use (6), (7) 1° § 4.751, so

$$\text{ceu}_{2n+1+\mu}(\pm z, q) = K_1 e^{\pm \mu z} \sum_{r=0}^{\infty} \rho_{2r+1} \cos[(2r+1)z \pm \phi_{2r+1}] \quad (b_{2n+1+\mu}), \quad (3, 4)$$

where  $K$  and  $K_1$  are normalizing constants defined in § 4.764. The above forms of solution are preferable in applications to those at (3), (4), 6° § 4.752 for the following reasons:

(i) One solution tends to zero, the other to infinity with  $z$ , whereas the even and odd solutions *both* tend to infinity with  $z$ .

(ii) In numerical work, tables of  $e^z$ ,  $e^{-z}$  are better to use than those of  $\sinh z$ ,  $\cosh z$ .

(iii) Analytical work using (1)–(4) is likely to be simpler than that involving the even and odd solutions.

It is of interest to remark that if we substitute

$$Z_0^{-1} (A_{2r+1}^{(2n+1-i\mu)} + A_{-2r-1}^{(2n+1-i\mu)}) = \rho_{2r+1} \cos \phi_{2r+1}, \quad (5)$$

$$\text{and} \quad -i Z_0^{-1} (A_{2r+1}^{(2n+1-i\mu)} - A_{-2r-1}^{(2n+1-i\mu)}) = \rho_{2r+1} \sin \phi_{2r+1}, \quad (6)$$

in the r.h.s. of

$$\left. \begin{array}{l} \text{ce} \\ \text{se} \end{array} \right\}_{2n+1-i\mu} (z, q) = \sum_{r=-\infty}^{\infty} A_{2r+1}^{(2n+1-i\mu)} \frac{\cos}{i \sin} (2r+1-i\mu)z, \quad (7, 8)^\dagger$$

the r.h.s. of (3), (4), 6° § 4.752 are reproduced, with  $r = 0$  to  $+\infty$ . Since  $\mu$  is real,  $2n+1-i\mu$  is complex, so (7), (8), and the corresponding functions derived by writing  $2n$ ,  $2r$  for  $(2n+1)$ ,  $(2r+1)$ , respectively, may be designated functions of complex order.

*Discrimination between solutions for the same  $q$  but different  $a$ .* We refer to § 4.760. On the upper and lower parts, and at the turning-point of an iso- $\mu$  curve, we use the symbols

$$\text{ceu}_{m+\bar{\mu}}, \quad \text{ceu}_{m+\mu}, \quad \text{ceu}_{m+\check{\mu}}, \quad \text{respectively.} \quad (9)$$

For example, if  $(a, q)$  lies on the upper part of the curve between  $b_{2n}$  and  $a_{2n}$ , we write

$$\text{ceu}_{2n+\bar{\mu}}(\pm z, q) = K e^{\pm \bar{\mu} z} \left\{ \bar{\rho}_0 + \sum_{r=1}^{\infty} \bar{\rho}_{2r} \cos(2rz \pm \bar{\phi}_{2r}) \right\}. \quad (10, 11)$$

† The r.h.s. of (7), (8) are the series for  $\text{ce}_{2n+1+\beta}(z, q)$  and  $\text{se}_{2n+1+\beta}(z, q)$  with  $-i\mu$  written for  $\beta$ .

Symbolism for solutions with the same  $a$  but different  $q$  may be devised by the reader.

**4.762. Degenerate forms of (1)–(4) § 4.761.** If  $a$  remains constant as  $(a, q)$  moves towards  $a_{2n}^\dagger$  in Fig. 11,  $\bar{\mu} \rightarrow 0$ , and in (1), (2) § 4.761  $K\bar{\rho}_0 \rightarrow A_0^{(2n)}$ ,  $K\bar{\rho}_{2r} \rightarrow A_{2r}^{(2n)}$ , and  $\bar{\phi}_{2r} \rightarrow 0$ ,  $r \geq 1$ . When  $\bar{\mu} = 0$ , by proper choice of  $K$ , we obtain  $\text{ce}_{2n}(z, q)$ . As  $(a, q)$  moves towards  $b_{2n}$ ,  $\mu \rightarrow 0$ , and  $\rho_0 \rightarrow 0$ ,  $K\rho_{2r} \rightarrow B_{2r}^{(2n)}$ ,  $\phi_{2r} \rightarrow -\frac{1}{2}\pi$ ,  $r \geq 1$ , so with  $\mu = 0$  we get  $\pm \text{se}_{2n}(z, q)$ . Similarly the degenerate forms of (3), (4) § 4.761 are  $\text{ce}_{2n+1}(z, q)$  and  $\pm \text{se}_{2n+1}(z, q)$ . These forms may also be derived from (3), (4) § 4.752.

**4.763. Functions of order  $m+\mu$ ,  $q < 0$ .** These are defined as follows:

$$\text{ceu}_{2n+\mu}(\pm z, -q) = (-1)^n e^{\mp \frac{1}{2}\pi\mu} \text{ceu}_{2n+\mu}[\pm(\frac{1}{2}\pi - z), q] \quad (b_{2n+\mu}) \quad (1, 2)$$

$$= (-1)^n K e^{\mp \mu z} \left\{ \rho_0 + \sum_{r=1}^{\infty} (-1)^r \rho_{2r} \cos(2rz \mp \phi_{2r}) \right\}. \quad (3, 4)$$

$$\text{ceu}_{2n+1+\mu}(\pm z, -q) = (-1)^n e^{\mp \frac{1}{2}\pi\mu} \text{ceu}_{2n+1+\mu}[\pm(\frac{1}{2}\pi - z), q] \quad (a_{2n+1+\mu}) \quad (5, 6)$$

$$= (-1)^n K_1 e^{\mp \mu z} \sum_{r=0}^{\infty} (-1)^r \rho_{2r+1} \sin[(2r+1)z \mp \phi_{2r+1}]. \quad (7, 8)$$

The r.h.s. of (7), (8) may be expressed in a cosine series by altering the argument in [ ] to  $[(2r+1)z - \frac{1}{2}\pi \mp \phi_{2r+1}]$ . The definition would then be in keeping with the notation  $\text{ceu}$ . When  $\bar{\mu} = 0$  in (3), (4), (7), (8) the functions degenerate to  $\text{ce}_{2n}(z, -q)$ ,  $\text{se}_{2n+1}(z, -q)$ ; when  $\underline{\mu} = 0$ , we get  $\mp \text{se}_{2n}(z, -q)$ ,  $\pm \text{ce}_{2n+1}(z, -q)$ , as may be expected from Fig. 11, where  $q < 0$ . The multiplier  $(-1)^n$  ensures that the signs of the degenerate forms are in accordance with the definitions in § 2.18, provided the upper signs are taken in the case  $\mu = 0$ .

**4.764. Normalization.** The rules must be such that the degenerate forms of the functions are those given in §§ 4.762, 4.763. Then we must have

$$K^2 \left[ 2\rho_0^2 + \sum_{r=1}^{\infty} \rho_{2r}^2 \right] = 1, \quad \text{or} \quad K = 1 / \left[ 2\rho_0^2 + \sum_{r=1}^{\infty} \rho_{2r}^2 \right]^{\frac{1}{2}}, \quad (1)$$

$$\text{and} \quad K_1^2 \sum_{r=0}^{\infty} \rho_{2r+1}^2 = 1, \quad \text{or} \quad K_1 = 1 / \left[ \sum_{r=0}^{\infty} \rho_{2r+1}^2 \right]^{\frac{1}{2}}. \quad (2)$$

† Except at  $a = m^2$ ,  $q = 0$ , the direction of approach to  $a_{2n}$  is immaterial, e.g. in § 4.711 the approach is with  $q$  constant.

**4.77. Convergence of solutions.** Substituting (1) 2° § 4.70 into Mathieu's equation and equating the coefficient of  $e^{2riz}$  to zero for  $r = -\infty$  to  $+\infty$ , yields the recurrence relation (1) § 4.750. This is a linear difference equation which may be treated on the lines of § 3.21. We find that

$$|u_{2r}| \sim q/4(r+1)^2 \rightarrow 0 \quad \text{as } r \rightarrow +\infty, \quad (1)$$

where  $u_{2r} = c_{2r+2}/c_{2r}$ . A similar result is obtained for  $r$  negative. Then as in §§ 3.21–3.23 it may be shown that (1) 2° § 4.70 and its derivatives are absolutely and uniformly convergent in any closed region of the  $z$ -plane. Hence the series, differentiable term by term, represent continuous functions. They may also be proved integrable term by term. These conclusions are valid for stable and also for unstable regions of the  $(a, q)$ -plane. Similar conclusions may also be drawn respecting the solutions given in §§ 4.761, 4.763.

**4.80. Solution of  $y'' + (a - 2q \cos 2z)y = 0$ ,  $a$  very large  $\gg q > 0$ .** The equation may be written

$$y'' + ay = (2q \cos 2z)y. \quad (1)$$

Neglecting the r.h.s., which is relatively small, by hypothesis, the formal solutions are  $\cos az^\dagger$ ,  $\sin az^\dagger$ . Substituting  $\cos az^\dagger$  for  $y$  on the r.h.s. of (1) leads to

$$y'' + ay = q[\cos(a^\dagger + 2)z + \cos(a^\dagger - 2)z], \quad (2)$$

of which the particular integral is

$$-\frac{1}{4}q \left[ \frac{\cos(a^\dagger + 2)z}{a^\dagger + 1} - \frac{\cos(a^\dagger - 2)z}{a^\dagger - 1} \right], \quad (3)$$

provided  $a \neq 1$ . Using this for  $y$  in the r.h.s. of (1) and solving again, the particular integral has terms in  $\cos(a^\dagger \pm 4)z$ , and so on. Hence the first solution of (1) may be expressed in the form

$$y_1 = \sum_{r=-\infty}^{\infty} c_r \cos(a^\dagger - 2r)z \quad (a^\dagger \text{ non-integral}). \quad (4)$$

If we use  $\sin a^\dagger z$  and proceed as above, the second solution is found to be

$$y_2 = \sum_{r=-\infty}^{\infty} c_r \sin(a^\dagger - 2r)z. \quad (5)$$

Substituting either (4) or (5) in the differential equation yields the recurrence relation

$$[a - (a^\dagger - 2r)^2]c_r - q(c_{r-1} + c_{r+1}) = 0, \quad (6)$$

or 
$$4r(a^\dagger - r)c_r - q(c_{r-1} + c_{r+1}) = 0. \quad (7)$$

If  $a^\dagger \gg r$ , we get the approximate relation

$$4rc_r - (q/a^\dagger)(c_{r-1} + c_{r+1}) = 0. \quad (8)$$

As in § 3.21, for convergence of (4), (5) we must have  $c_r \rightarrow 0$  as  $r \rightarrow \pm\infty$ .

Now a recurrence relation for the  $J$ -Bessel function is

$$4rJ_r(u) - 2u(J_{r-1} + J_{r+1}) = 0, \quad (9)$$

and since  $J_r \rightarrow 0$  as  $r \rightarrow \pm\infty$ ,  $c_r = \text{constant} \times J_r$ . If we take the constant to be unity (for simplicity) we get

$$c_r = J_r(q/2a^\dagger). \quad (10)$$

When  $q/2a^\dagger \ll r$ , the B.F. may be represented by the first term of its expansion, so  $c_r \simeq (q/4a^\dagger)^r/r!$  giving  $c_r/c_{r-1} = q/4ra^\dagger$ . Thus the coefficients decrease with increase in  $r$  and may be neglected if  $r > r_0$ , where  $a^\dagger \gg r_0$ . Accordingly, approximate solutions of Mathieu's equation, subject to the conditions  $a$  very large  $\gg q > 0$ ,  $a^\dagger \gg r_0$ , are

$$y_1 \simeq \sum_{r=-r_0}^{r_0} J_r(q/2a^\dagger) \cos(a^\dagger - 2r)z \quad (11)$$

and

$$y_2 \simeq \sum_{r=-r_0}^{r_0} J_r(q/2a^\dagger) \sin(a^\dagger - 2r)z. \quad (12)^\dagger$$

Hence the approximate complete solution with two arbitrary constants is

$$y \simeq Ay_1 + By_2 = C \sum_{r=-r_0}^{r_0} J_r(q/2a^\dagger) \cos[(a^\dagger - 2r)z - \alpha], \quad (13)$$

where  $C = (A^2 + B^2)^\dagger$ ,  $\alpha = \tan^{-1}(B/A)$ . Since (13) is bounded in  $z$ , the point  $(a, q)$  must lie in a stable region of the plane (see Fig. 8).

#### 4.81. Transformation of Mathieu's equation to a Riccati

type. Write  $y = e^{\nu \int w dz}$ , where  $\nu = a^\dagger$ , and  $w(z)$  is a differentiable function of  $z$ . Then

$$dy/dz = \nu wy, \quad d^2y/dz^2 = \nu y(dw/dz + \nu w^2). \quad (1)$$

If we put  $[1 - (2q/a) \cos 2z] = \rho^2$ , Mathieu's equation becomes

† If  $r$  covered the range  $-\infty$  to  $+\infty$ , it is easy to show by aid of formulae (6), (7), p. 42, reference [202], that the respective representations of (11), (12) would be  $\frac{\cos}{\sin} \left[ a^\dagger \left( z - \frac{q}{2a} \sin 2z \right) \right]$ . This form is obtained at (7), (8) § 4.81 by a different method.

$y'' + a\rho^2 y = 0$ . Using the above substitution it is transformed to the Riccati type [133]

$$\frac{1}{v} \frac{dw}{dz} + w^2 + \rho^2 = 0, \quad (2)$$

since  $y \neq 0$ . Now if  $a \gg q > 0$ ,  $a$  being very large, the first member of (2) may be neglected, and we get

$$w = \pm i\rho = \pm i \left( 1 - \frac{2q}{a} \cos 2z \right)^{\frac{1}{2}} \quad (3)$$

$$\simeq \pm i \left( 1 - \frac{q}{a} \cos 2z \right). \quad (4)$$

Hence 
$$v \int^z w dz \simeq \pm ia^{\frac{1}{2}} \left( z - \frac{q}{2a} \sin 2z \right), \quad (5)$$

and, therefore, 
$$y = e^{\nu \int^z w dz} \simeq e^{\pm ia^{\frac{1}{2}} [z - (q/2a) \sin 2z]}. \quad (6)$$

Then by the theory of linear differential equations, we may combine the two solutions in (6) as follows:

$$y_1 \simeq \frac{1}{2} \{ e^{ia^{\frac{1}{2}} [z - (q/2a) \sin 2z]} + e^{-ia^{\frac{1}{2}} [z - (q/2a) \sin 2z]} \} = \cos \left[ a^{\frac{1}{2}} \left( z - \frac{q}{2a} \sin 2z \right) \right], \quad (7)$$

and

$$y_2 \simeq \frac{1}{2i} \{ e^{ia^{\frac{1}{2}} [z - (q/2a) \sin 2z]} - e^{-ia^{\frac{1}{2}} [z - (q/2a) \sin 2z]} \} = \sin \left[ a^{\frac{1}{2}} \left( z - \frac{q}{2a} \sin 2z \right) \right]. \quad (8)$$

Combining (7), (8) with two arbitrary constants leads to

$$y = \bar{A}y_1 + \bar{B}y_2 = \bar{C} \cos \left[ a^{\frac{1}{2}} \left( z - \frac{q}{2a} \sin 2z \right) - \bar{\alpha} \right], \quad (9)$$

where  $\bar{C} = (\bar{A}^2 + \bar{B}^2)^{\frac{1}{2}}$ , and  $\bar{\alpha} = \tan^{-1}(\bar{B}/\bar{A})$ . Expanding (9) gives

$$y \simeq \bar{C} \left\{ \cos \left( \frac{q}{2a^{\frac{1}{2}}} \sin 2z \right) \cos(a^{\frac{1}{2}} z - \bar{\alpha}) + \sin \left( \frac{q}{2a^{\frac{1}{2}}} \sin 2z \right) \sin(a^{\frac{1}{2}} z - \bar{\alpha}) \right\}. \quad (10)$$

Expressing the first factor of each member of the r.h.s. in B.F. series [202, p. 42], we get, with  $h = (q/2a^{\frac{1}{2}})$ , which may be  $\gg 1$ ,

$$y \simeq \bar{C} \left\{ \left[ J_0(h) + 2 \sum_{r=1}^{\infty} J_{2r}(h) \cos 4rz \right] \cos(a^{\frac{1}{2}} z - \bar{\alpha}) + \left[ 2 \sum_{r=0}^{\infty} J_{2r+1}(h) \sin(4r+2)z \right] \sin(a^{\frac{1}{2}} z - \bar{\alpha}) \right\}, \quad (11)$$

$$= \bar{C} \sum_{r=-\infty}^{\infty} J_r(h) \cos[(a^{\frac{1}{2}} - 2r)z - \bar{\alpha}]. \quad (12)$$

This has the same form as (13) § 4.80, but in (12) the summation covers a doubly infinite range of  $r$ . Owing to the rapid decrease in  $J_r(h)$  beyond  $r = r_0$ , a finite range of  $r$  is adequate in applications.

The approximate solution of  $y'' + (a + 2q \cos 2z)y = 0$  is obtained from (12) by writing  $-h$  for  $h$ . Since  $J_r(-h) = (-1)^r J_r(h)$ , we get

$$y \simeq \bar{C} \sum_{r=-\infty}^{\infty} (-1)^r J_r(h) \cos[(a^{\frac{1}{2}} - 2r)z - \bar{\alpha}]. \quad (13)$$

As in § 4.80 the point  $(a, q)$  must lie in a stable region of Fig. 8.

#### 4.82. More accurate approximate solution of

$$y'' + (a - 2q \cos 2z)y = 0.$$

The solution at (9) § 4.81 is a circular function with periodically varying argument, but constant amplitude factor  $\bar{C}$ . We shall now derive a closer approximation in which the amplitude factor is periodic in  $z$ . We start with (2) § 4.81, and assume that [133]

$$w = w_0 + \frac{1}{\nu} w_1 + \frac{1}{\nu^2} w_2 + \dots, \quad (1)$$

the  $w(z)$  being differentiable functions of  $z$ . Then

$$w^2 = w_0^2 + \frac{2}{\nu} w_0 w_1 + \frac{1}{\nu^2} (w_1^2 + 2w_0 w_2) + \dots, \quad (2)$$

$$\frac{1}{\nu} \frac{dw}{dz} = \frac{1}{\nu} w'_0 + \frac{1}{\nu^2} w'_1 + \frac{1}{\nu^3} w'_2 + \dots \quad (3)$$

Substituting (2), (3) into (2) § 4.81 gives

$$w_0^2 + \rho^2 + \frac{1}{\nu} (w'_0 + 2w_0 w_1) + \frac{1}{\nu^2} (w_1^2 + 2w_0 w_2) + \dots = 0. \quad (4)$$

Equating the coefficients of  $\nu^0, \nu^{-1}, \nu^{-2}, \dots$  to zero yields

$$w_0^2 + \rho^2 = 0, \quad (5)$$

$$w'_0 + 2w_0 w_1 = 0, \quad (6)$$

$$w'_1 + w_1^2 + 2w_0 w_2 = 0, \quad (7)$$

$$\dots \dots \dots$$

$$\text{From (5), } w_0 = \pm i\rho, \text{ so } \nu \int w_0 dz = \pm i\nu \int \rho dz: \quad (8)$$

From (6),

$$\begin{aligned} w_1 &= -\frac{1}{2} \frac{w'_0}{w_0}, \text{ so } \int w_1 dz = -\frac{1}{2} \int \frac{dw_0}{w_0} + \text{constant} \\ &= \log A w_0^{-\frac{1}{2}} = \log(A\rho^{-\frac{1}{2}}) \mp \frac{1}{4}\pi i. \end{aligned} \quad (9)$$

From (7),

$$\begin{aligned} w_2 &= -\left(\frac{w_1' + w_1^2}{2w_0}\right) = \frac{1}{4}\left[\frac{w_0''}{w_0^2} - \frac{3}{2}\frac{w_0'^2}{w_0^3}\right] \\ &= \mp \frac{i}{8\rho^3}(2\rho\rho'' - 3\rho'^2), \end{aligned}$$

so 
$$\frac{1}{\nu} \int^z w_2 dz = \mp \frac{i}{8\nu} \int^z \left(\frac{2\rho\rho'' - 3\rho'^2}{\rho^3}\right) dz. \quad (10)$$

Then by (1), (8)–(10), if  $|a| \gg 1$ ,  $|a| > |2q|$ , to a second approximation

$$\nu \int^z w dz = \pm i\nu \int^z \rho dz + \log(A\rho^{-1}) \mp \frac{1}{4}\pi i \mp \frac{ia^{-1}}{8} \int^z \left(\frac{2\rho\rho'' - 3\rho'^2}{\rho^3}\right) dz. \quad (11)$$

Hence

$$e^{\nu \int^z w dz} = Be^{\nu \int^z w dz} \simeq (\text{constant})\rho^{-1}e^{\pm ia^{\frac{1}{2}} \int_0^z [\rho - (2\rho\rho'' - 3\rho'^2)/8a\rho^3] dz}, \quad (12)$$

the factor  $e^{\mp \frac{1}{4}\pi i}$  being absorbed in the constant.

Combining the two solutions as in § 4.81 we get

$$\frac{y_1(z)}{y_2(z)} \simeq \text{constant } \rho^{-\frac{1}{2}} \frac{\cos\left[a^{\frac{1}{2}} \int_0^z \varphi(z) dz\right]}{\sin\left[a^{\frac{1}{2}} \int_0^z \varphi(z) dz\right]}, \quad (13)$$

where  $\varphi(z) = \rho - (2\rho\rho'' - 3\rho'^2)/8a\rho^3$ . Then (13) are independent solutions of  $y'' + a\rho^2 y = 0$ . A representative graph is given in Fig. 10A.

If  $a \gg 1$ ,  $a > 2q > 0$ , both real, the solutions (13) are bounded, so the point  $(a, q)$  must lie in a stable region of Fig. 8. If  $|a| \gg 1$ ,  $|a| \gg |2q|$ , and the argument in  $[\ ]$  is imaginary or complex, the solutions are unstable, so  $(a, q)$  then lies in an unstable region of Fig. 8.

Omitting the terms in  $\rho'$ ,  $\rho''$  in  $\varphi(z)$ , we get

$$\begin{aligned} a^{\frac{1}{2}} \int_0^z \phi(z) dz &= \int_0^z (a - 2q \cos 2z)^{\frac{1}{2}} dz \\ &= (a + 2q)^{\frac{1}{2}} \int_0^z (1 - \lambda^2 \cos^2 u)^{\frac{1}{2}} du \\ &= (a + 2q)^{\frac{1}{2}} [E(\lambda, \tfrac{1}{2}\pi) - E(\lambda, \tfrac{1}{2}\pi - z)] \\ &= (a + 2q)^{\frac{1}{2}} E_1(\lambda, z), \end{aligned} \quad (14)$$

where  $E(\lambda, z)$  is an incomplete elliptic integral of the second kind

with modulus  $\lambda = 2[q/(a+2q)]^{\frac{1}{2}} < 1$ . Then we may write (13) in the form

$$\frac{y_1(z)}{y_2} \simeq \frac{\text{constant}}{(a-2q \cos 2z)^{\frac{1}{2}}} \cos [(a+2q)^{\frac{1}{2}} E_1(\lambda, z)]. \quad (15)$$

FIG. 10 (A). Curves showing combined amplitude and frequency modulation; see (13) § 4.82 and (4) § 15.25.

When  $|2q| \gg |a|$  the approximate solution of Mathieu's equation may be derived as shown in 2° § 6.20.

The argument of the circular functions in (15) is periodic, so the frequency of repetition of the function fluctuates. It is defined to be

$$\begin{aligned} f &= \omega/2\pi = \frac{1}{2\pi} \frac{d}{dz} [(a+2q)^{\frac{1}{2}} E_1(\lambda, z)] \\ &= \frac{1}{2\pi} (a+2q)^{\frac{1}{2}} (1 - \lambda^2 \cos^2 z)^{\frac{1}{2}}. \end{aligned} \quad (16)$$

The 'periodicity' or reciprocal of the frequency is

$$1/f = 2\pi/(a+2q)^{\frac{1}{2}}(1-\lambda^2 \cos^2 z)^{\frac{1}{2}}, \quad (17)$$

which differs from that when  $q = 0$ , namely,  $2\pi a^{-\frac{1}{2}}$ .

From (15) the ratio (maximum/minimum) amplitude factor is

$$[(a+2q)/(a-2q)]^{\frac{1}{2}}. \quad (18)$$

FIG. 10 (B). As at Fig. 10A, but for the derivative, e.g.  $I_1(t)$  in (9) § 15.25.

**4.83. Equation of the type**  $y'' + 2\kappa y' + (\bar{a} - 2q \cos 2z)y = 0$ . Assume that  $\kappa$ ,  $\bar{a}$ ,  $q$  are real, with  $\kappa \geq 0$ ,  $q \geq 0$ . Substituting  $y = e^{-\kappa z}u(z)$  into the equation, we obtain the Mathieu equation

$$u'' + (a - 2q \cos 2z)u = 0, \quad (1)$$

with  $a = (\bar{a} - \kappa^2)$ . If the parametric point  $(a, q)$  lies within a stable region of Fig. 8, the solution of the original equation takes the form

(see (2), (5), 1° § 4.70)

$$y_1(z) = e^{-\kappa z} \sum_{r=-\infty}^{\infty} c_{2r} \cos(2r+\beta)z \quad \text{or} \quad e^{-\kappa z} \sum_{r=-\infty}^{\infty} c_{2r+1} \cos(2r+1+\beta)z, \quad (2)$$

and

$$y_2(z) = e^{-\kappa z} \sum_{r=-\infty}^{\infty} c_{2r} \sin(2r+\beta)z \quad \text{or} \quad e^{-\kappa z} \sum_{r=-\infty}^{\infty} c_{2r+1} \sin(2r+1+\beta)z$$

( $0 < \beta < 1$ ,  $\beta$  real). (3)

The solutions (2), (3) are proportional to  $e^{-\kappa z} \text{ce}_{m+\beta}(z, q)$  and  $e^{-\kappa z} \text{se}_{m+\beta}(z, q)$  respectively. These may be regarded as damped Mathieu functions of fractional order.

If  $(a, q)$  lies in an unstable region of Fig. 8, the solution of (1) takes the form at (1) or (3), 2° § 4.70. Thus the solution of the original equation is given by

$$y_1(z) = e^{(\mu-\kappa)z} \sum_{r=-\infty}^{\infty} c_{2r} e^{2riz} \quad \text{or} \quad e^{(\mu-\kappa)z} \sum_{r=-\infty}^{\infty} c_{2r+1} e^{(2r+1)zi} \quad (4)$$

and

$$y_2(z) = e^{-(\mu+\kappa)z} \sum_{r=-\infty}^{\infty} c_{2r} e^{-2riz} \quad \text{or} \quad e^{-(\mu+\kappa)z} \sum_{r=-\infty}^{\infty} c_{2r+1} e^{-(2r+1)zi}. \quad (5)$$

$y_1$  is stable and  $\rightarrow 0$  as  $z \rightarrow +\infty$ , if  $\kappa > \mu > 0$ .

$y_1$  is unstable and  $\rightarrow \pm\infty$  as  $z \rightarrow +\infty$ , if  $0 \leq \kappa < \mu$ .

$y_1$  is neutral and periodic with period  $\pi$  or  $2\pi$ , if  $\kappa = \mu > 0$ .

$y_2$  is stable and  $\rightarrow 0$  as  $z \rightarrow +\infty$  in each case.

Conditions of solution are assumed (see 2° § 4.70) such that  $\mu$  is real. If it is complex,  $R(\mu)$  is to be understood above; also  $z$  is real.

**4.84. Iso- $\beta\mu$  stability chart.** This is illustrated in Fig. 11. The iso- $\beta$  curves lie in the stable regions for Mathieu's equation, while the iso- $\mu$  curves lie in the unstable regions. Each iso- $\beta$  curve is single-valued in  $q$ , but except for the region below  $a_0$ , each iso- $\mu$  is double-valued in  $q$ . For constant  $\mu$ ,  $q$  at the turning-point of the iso- $\mu$  curve increases with increase in  $a$ , e.g. if  $\mu = 0.1$ ,  $q \simeq 0.21$  when  $a \simeq 1$ , but  $q \simeq 1.3$  when  $a \simeq 4.22$ .

Suppose that in (1) § 4.83,  $a = 1$ ,  $q \simeq 0.21$ , then  $(a, q)$  lies on the iso- $\mu$  curve  $\mu = 0.1$  between  $b_1$  and  $a_1$ . Thus the solution of the equation is unstable. Referring to the original equation, if  $\kappa > 0.1$ , the solution is stable and tends to zero as  $z \rightarrow +\infty$ . Since  $(1, 0.21)$  lies between the characteristics for  $\text{se}_1$  and  $\text{ce}_1$ , by 2° § 4.70 the solutions take the form at the extreme right of (4), (5) § 4.83. If  $\kappa = 0.1$ ,  $(\mu - \kappa) = 0$ , so one solution is periodic with period  $2\pi$ , while the other

$\rightarrow 0$  as  $z \rightarrow +\infty$ . The iso- $\mu$  curve  $\mu = 0.1$  is its characteristic or boundary curve separating the stable and unstable regions. Thus for

$$y'' + 0.2y' + (\bar{a} - 2q \cos 2z)y = 0, \quad (1)$$

the stable regions are larger than those for Mathieu's equation, by

FIG. 11. Iso- $\beta\mu$  stability chart for Mathieu functions of fractional order. The iso- $\beta$  and iso- $\mu$  curves are symmetrical about the  $\alpha$ -axis.

the areas included between the iso- $\mu$  curves  $\mu = 0.1$  and the  $b_m$ ,  $a_m$  curves to which they are asymptotic. The range of  $\mu$  is  $-\infty < \mu < \infty$ : if positive it is  $0 \leq \mu < \infty$ .

**4.85. Solution of  $y'' + 2\kappa y' + (\bar{a} - 2q \cos 2z)y = 0$ , when  $\bar{a} \gg 2q > 0$ ,  $\bar{a} \gg \kappa^2$ .** We assume that the point  $[(\bar{a} - \kappa^2), q]$  lies in a stable region of Figs. 8 or 11. Then by § 4.83  $y = e^{-\kappa z}u(z)$ ,  $u(z)$  being a solution of

(1) § 4.83. Hence its value is given by § 4.81 with  $a = \bar{a} - \kappa^2$ . Accordingly, with  $h_1 = q/2(\bar{a} - \kappa^2)^{\frac{1}{2}}$ , we get

$$y \simeq C_1 \sum_{r=-\infty}^{\infty} J_r(h_1) e^{-\kappa z} \cos[(\bar{a} - \kappa^2)^{\frac{1}{2}} - 2r]z - \alpha_1]. \quad (1)$$

**4.86. More accurate approximate solution of equation in § 4.85.** It is evident that the required solution may be derived on writing  $(\bar{a} - \kappa^2)$  for  $a$  in (15) § 4.82 and multiplying by  $e^{-\kappa z}$ . Thus we get

$$\frac{y_1(z)}{y_2} \simeq \frac{\text{a constant } e^{-\kappa z}}{(\bar{a} - \kappa^2 - 2q \cos 2z)^{\frac{1}{2}} \sin} [(\bar{a} - \kappa^2 + 2q)^{\frac{1}{2}} E_1(\lambda_1, z)], \quad (1)$$

where  $\lambda_1^2 = 4q/(\bar{a} - \kappa^2 + 2q)$ , and the conditions respecting  $(a, q)$  in § 4.82 obtain. In the foregoing cases, when  $q$  is negative the solution is obtained by writing  $(\frac{1}{2}\pi - z)$  for  $z$  in that already given, excepting the exponential index.

**4.90. Solution of  $y'' + (a - 2q \cos 2z)y = 0$  in an unstable region of the  $(a, q)$ -plane.** In § 4.12 et seq. the solution was shown to have the form

$$\left. \begin{aligned} y_1(z) &= e^{\mu z} \phi(z), \\ y_2 &= e^{-\mu z} \phi(-z). \end{aligned} \right\} \quad (1)$$

Now  $\phi(z)$  is periodic in  $z$  with period  $\pi$  or  $2\pi$ , so it can be expressed in a series of Mathieu functions  $\text{se}_{2p}$ ,  $\text{ce}_{2p}$  or  $\text{se}_{2p+1}$ ,  $\text{ce}_{2p+1}$ . In accordance with 2° § 4.70, for  $(a, q)$  in an unstable region between the curves  $b_{2p}$  and  $a_{2p}$ , we write

$$\phi(z) = \sum_{p=0}^{\infty} [C_{2p} \text{ce}_{2p}(z, q) + S_{2p} \text{se}_{2p}(z, q)]; \quad (2)$$

and for  $(a, q)$  in an unstable region between  $b_{2p+1}$  and  $a_{2p+1}$  we write

$$\phi(z) = \sum_{p=0}^{\infty} [C_{2p+1} \text{ce}_{2p+1}(z, q) + S_{2p+1} \text{se}_{2p+1}(z, q)], \quad (3)$$

the  $C, S$  being determinable constants. Putting  $r = 2p$  or  $2p+1$ , as the case may be, our proposed solution takes the form

$$\frac{y_1(z)}{y_2} = e^{\pm \mu z} \sum_{p=0}^{\infty} [C_r \text{ce}_r(z, q) \pm S_r \text{se}_r(z, q)]. \quad (4)$$

Substituting  $y_1(z)$  from (1) into Mathieu's equation yields

$$\phi'' + 2\mu\phi' + (a + \mu^2 - 2q \cos 2z)\phi = 0. \quad (5)$$

From (2), (3) with  $r = 2p$  or  $2p+1$ , assuming uniform convergence,

$$\begin{aligned} \phi''(z) &= \sum_{p=0}^{\infty} (C_r \text{ce}_r'' + S_r \text{se}_r'') \\ &= \sum_{p=0}^{\infty} [C_r (2q \cos 2z - a_r) \text{ce}_r + S_r (2q \cos 2z - b_r) \text{se}_r], \end{aligned} \quad (6)$$

where  $a_r, b_r$  are the characteristic numbers for  $ce_r, se_r$ , respectively, corresponding to the value of  $q$  used in the equation. Also

$$\phi'(z) = \sum_{p=0}^{\infty} (C_r ce'_r + S_r se'_r). \quad (7)$$

Substituting from (2), (3), (6), (7) into (5) leads to

$$\sum_{p=0}^{\infty} [C_r(2q \cos 2z - a_r)ce_r + S_r(2q \cos 2z - b_r)se_r] + 2\mu \sum_{p=0}^{\infty} (C_r ce'_r + S_r se'_r) + (a + \mu^2 - 2q \cos 2z) \sum_{p=0}^{\infty} (C_r ce_r + S_r se_r) = 0. \quad (8)$$

The series being assumed absolutely convergent, (8) may be written

$$\sum_{p=0}^{\infty} C_r(a - a_r + \mu^2)ce_r + \sum_{p=0}^{\infty} S_r(a - b_r + \mu^2)se_r + 2\mu \sum_{p=0}^{\infty} (C_r ce'_r + S_r se'_r) = 0. \quad (9)$$

Multiplying (9) by  $ce_s$  and integrating with respect to  $z$  from 0 to  $2\pi$ , by aid of §§ 2.19, 2.21, 14.42, we get

$$\pi C_s(a - a_s + \mu^2) + 2\mu \int_0^{2\pi} \sum_{p=0}^{\infty} S_r se'_r ce_s dz = 0, \quad (10)$$

$$\text{or} \quad \pi C_s(a - a_s + \mu^2) + 2\mu \sum_{p=0}^{\infty} S_r K_{rs} = 0, \quad (11)$$

$$\text{where} \quad K_{rs} = \int_0^{2\pi} se'_r ce_s dz.$$

Multiplying (9) by  $se_s$  and integrating as above leads to

$$\pi S_s(a - b_s + \mu^2) + 2\mu \int_0^{2\pi} \sum_{p=0}^{\infty} C_r ce'_r se_s dz = 0. \quad (12)$$

By (2) § 14.42,  $\int_0^{2\pi} ce'_r se_s dz = -\int_0^{2\pi} se'_s ce_r dz = -K_{sr}$ , and by virtue of uniform convergence (12) may be written

$$\pi S_s(a - b_s + \mu^2) - 2\mu \sum_{p=0}^{\infty} C_r K_{sr} = 0, \quad (13)$$

$$\text{so} \quad \pi S_r(a - b_r + \mu^2) - 2\mu \sum_{j=0}^{\infty} C_s K_{rs} = 0, \quad (14)$$

with  $s = 2j$  or  $2j+1$ , as the case may be. Writing  $m$  for  $s$  in (11) and substituting for  $S_r$  from (14) yields

$$\pi^2 C_m(a - a_m + \mu^2) + 4\mu^2 \sum_{p=0}^{\infty} \sum_{j=0}^{\infty} [C_s K_{rs} K_{rm} / (a - b_r + \mu^2)] = 0. \quad (15)$$

The eliminant of this set of equations is—in effect—an equation from which  $\mu$  may be determined (compare (3) § 4.20).

**4.91. Approximate solution when  $a \gg q$  real  $> 0$ .** In this case we see from Fig. 8 that  $a$  lies in a narrow unstable region where  $b_m < a < a_m$ . It is to be expected, therefore, that the dominant terms in (2), (3) § 4.90 will be of order  $m$ . Accordingly as an approximation we shall take

$$\phi(z) \simeq C_m \text{ce}_m(z, q) + S_m \text{se}_m(z, q), \quad (1)$$

the other  $C, S$  being assumed negligible by comparison. Then by (1) and (1) § 4.90

$$y_1(z) \simeq e^{\mu z} [C_m \text{ce}_m(z, q) + S_m \text{se}_m(z, q)] \quad (2)$$

and 
$$y_2(z) \simeq e^{-\mu z} [C_m \text{ce}_m(z, q) - S_m \text{se}_m(z, q)]. \quad (3)$$

Thus (15) § 4.90 may be written

$$C_m [\pi^2(a - a_m + \mu^2) + 4\mu^2 K_{mm}^2 / (a - b_m + \mu^2)] = 0. \quad (4)$$

Now  $C_m \neq 0$ , so (4) gives

$$\frac{4\mu^2}{\pi^2} K_{mm}^2 + (a - a_m + \mu^2)(a - b_m + \mu^2) = 0. \quad (5)$$

Neglecting  $\mu^4$ , on the assumption that  $|\mu| \ll 1$ , we obtain from (5)

$$\mu^2 = (a_m - a)(a - b_m) / \left( \frac{4}{\pi^2} K_{mm}^2 + 2a - a_m - b_m \right). \quad (6)$$

When  $q$  is small enough, by §§ 3.32, 14.42 and tabular values of the coefficients  $A, B$  [95], we find that  $K_{mm}^2 \simeq \pi^2 m^2$ , while

$$(2a - a_m - b_m) \ll 4m^2.$$

Hence we may express (6) in the approximate form

$$\mu \simeq \pm [(a_m - a)(a - b_m)]^{1/2} / 2m. \quad (7)$$

In Fig. 12,  $(a_2 - a)$ ,  $(a - b_2)$  are the segments of the line  $a_2 b_2$ . Their product is a maximum when  $a$  is the mid-point. Then for an assigned  $q$

$$\mu_{\max} \simeq (a_m - b_m) / 4m. \quad (8)$$

By virtue of this property, when  $q$  is small enough the turning-point of an iso- $\mu$  curve occurs approximately midway between the bounding curves for the region, i.e.  $b_{2n}$ ,  $a_{2n}$  or  $b_{2n+1}$ ,  $a_{2n+1}$  as the case may be. Also, when  $q$  is small enough, the series for  $a_m$ ,  $b_m$  in § 2.151 may be used in computing  $\mu$ , as exemplified in § 4.92.

To the degree of approximation in (1), equations (11), (13) § 4.90 become

$$\pi C_s(a - a_s + \mu^2) + 2\mu S_m K_{ms} = 0 \quad (9)$$

and 
$$\pi S_s(a - b_s + \mu^2) - 2\mu C_m K_{sm} = 0. \quad (10)$$

In particular when  $s = m$ , we get

$$\pi C_m(a - a_m + \mu^2) + 2\mu S_m K_{mm} = 0 \quad (11)$$

and 
$$\pi S_m(a - b_m + \mu^2) - 2\mu C_m K_{mm} = 0. \quad (12)$$

From (12) 
$$S_m = 2\mu C_m K_{mm} / \pi(a - b_m + \mu^2). \quad (13)$$

FIG. 12. Illustrating calculation of  $\beta$ ,  $\mu$ .

Substituting for  $2\mu K_{mm}/\pi$  from (5) into (13) yields

$$S_m = C_m \left( \frac{a_m - a - \mu^2}{a - b_m + \mu^2} \right)^{\frac{1}{2}}. \quad (14)$$

Substituting for  $\mu$  from (5) and for  $S_m$  from (13) into (9), we obtain

$$C_s = -C_m \frac{K_{ms}}{K_{mm}} \left( \frac{a_m - a - \mu^2}{a - a_s + \mu^2} \right). \quad (15)$$

Substituting for  $\mu$  from (5) into (10) leads to

$$S_s = C_m \frac{K_{sm}}{K_{mm}} \frac{[(a_m - a - \mu^2)(a - b_m + \mu^2)]^{\frac{1}{2}}}{(a - b_s + \mu^2)}. \quad (16)$$

In (15), (16) it may be remarked that  $s$  corresponds to  $r$  in (4) § 4.90.

**4.92. Example.** Find a first approximation to  $y_1(z)$  for the equation  $y'' + (1 - 0.32 \cos 2z)y = 0$ .

Here  $a = 1$ ,  $q = 0.16$ , and the point  $(a, q)$  lies in an unstable region of the plane between the curves  $b_1$ ,  $a_1$  in Fig. 8. Then from (2), (3) § 2.151

$$b_1 \simeq 1 - q - \frac{1}{8}q^2 \quad (1)$$

$$\text{and} \quad a_1 \simeq 1 + q - \frac{1}{8}q^2. \quad (2)$$

Thus

$$\left. \begin{aligned} (a - b_1) &\simeq q + \frac{1}{8}q^2, \\ (a_1 - a) &\simeq q - \frac{1}{8}q^2, \end{aligned} \right\} \text{ so } (a_1 - a)(a - b_1) \simeq q^2 - \frac{1}{64}q^4 \simeq q^2. \quad (3)$$

Hence from (3) above, and (7) § 4.91 with  $m = 1$ , we obtain

$$\mu \simeq \pm \frac{1}{2}q = \pm 0.08, \quad (4)$$

which is the value calculated in § 5.33 using an entirely different method.

Substituting for the various quantities in (14) § 4.91 with  $m = 1$ , we have

$$\begin{aligned} S_1 &\simeq C_1 \left( \frac{q - \frac{1}{8}q^2 - \frac{1}{4}q^2}{q + \frac{1}{8}q^2 + \frac{1}{4}q^2} \right)^{\frac{1}{2}} = C_1 \left( \frac{1 - \frac{3}{8}q}{1 + \frac{3}{8}q} \right)^{\frac{1}{2}} \\ &\simeq 0.94 C_1. \dagger \end{aligned} \quad (5)$$

Substituting for  $\mu$ ,  $S_1$ ,  $q$  in (2) § 4.91 gives a first approximation to  $y_1(z)$ , namely,

$$y_1(z) \simeq C_1 e^{0.08z} [\text{ce}_1(z, 0.16) + 0.94 \text{se}_1(z, 0.16)], \quad (6)$$

$C_1$  being arbitrary. Also writing  $-z$  for  $z$ , the second solution is

$$y_2(z) \simeq C_1 e^{-0.08z} [\text{ce}_1(z, 0.16) - 0.94 \text{se}_1(z, 0.16)], \quad (7)$$

and the complete solution with two arbitrary constants is, therefore,

$$y \simeq A e^{-0.08z} [\text{ce}_1 - 0.94 \text{se}_1] + B e^{0.08z} [\text{ce}_1 + 0.94 \text{se}_1], \quad (8)$$

the constant  $C_1$  being absorbed in  $A$ ,  $B$ .

**4.93. Solution of  $y'' + (a - 2q \cos 2z)y = f(z)$ .** This is given by (13) § 6.22 to which section reference should be made.

**4.94. Solution of  $y'' + 2\kappa y' + (\bar{a} - 2q \cos 2z)y = f(z)$ .** The substitution  $y = e^{-\kappa z} u(z)$  transforms the equation to

$$u'' + (a - 2q \cos 2z)u = e^{\kappa z} f(z), \quad (1)$$

with  $a = (\bar{a} - \kappa^2)$ . Then the solution of (1) is given by (13) § 6.22.

If  $q < 0$ , or if  $\cosh$  be written for  $\cos$ ,  $-\infty < q < \infty$ , in this section and in § 4.93, the procedure is first to obtain the solution with the r.h.s. zero, and then use (13) § 6.22.

† The sign of this term is that of (13) § 4.91, where we assume  $\mu$  is positive.

# V

## NUMERICAL SOLUTION OF EQUATIONS

**5.10. Calculation of  $\beta$ ,  $\mu$ , with  $q$  small and positive.** Provided  $a \neq m^2$ , (4) § 4.74 or (2) § 4.23 may be used. Also (14) § 4.30, or one of that type suited to the region of the  $(a, q)$ -plane where  $a$ ,  $q$  lies, is valid for  $a$  integral or fractional, provided  $q$  is not too large. If an iso- $\beta\mu$  stability chart of the type in Fig. 11, but 2 or 3 feet square, and covering a greater range of  $a$  were available,  $\beta$ ,  $\mu$  could be obtained directly. If  $a^\dagger$  and  $q$  were plotted, the vertical spacing would be more uniform than that in Fig. 11, while interpolation near the  $a^\dagger$ -axis would be almost linear. Tabular values of  $a^\dagger$ ,  $q$ , and  $\beta$  would serve the same purpose and facilitate interpolation.

1°. Calculate  $\beta$  for  $y'' + (2 - 0.32 \cos 2z)y = 0$ . Here  $a = 2$ ,  $q = 0.16$  and the parametric point lies in a stable region of Figs. 8, 11, between  $a_1$  and  $b_2$ . First we obtain an approximation. On the  $a$ -axis  $\beta =$  fractional part of  $a^\dagger$ , so taking  $a = 2$ ,  $\beta = 2^\dagger - 1 \simeq 0.414$ . This is an approximation to  $\beta$  at  $q = 0.16$ . In Fig. 11 the  $\beta$  const. curve through  $(2, 0.16)$  meets the  $a$ -axis where  $a < 2$ . Thus the correct value of  $\beta < 0.414$ .

*Method 1.* Using (4) § 4.74 and omitting the term in  $q^6$ , we get

$$1 + \beta = \left[ 2 - \frac{0.16^2}{2 - 0.16^2} + \frac{17 \times 0.16^4}{32 \times 2} \right]^{\frac{1}{2}} = 1.9872^\dagger,$$

so

$$\beta = 0.4097. \quad (1)$$

As we shall see in § 5.20, this is a fairly close result.

*Method 2.* We apply (14) § 4.30, but have to calculate  $\sin 2\sigma$  first. Then (12) § 4.30 may be abbreviated and written in the approximate form

$$\frac{1}{4}q^2 \left( 1 - \frac{11}{64}q^2 \right) \cos^2 2\sigma - q \left( 1 - \frac{1}{64}q^2 \right) \cos 2\sigma + \frac{65}{1536}q^4 - \frac{3}{8}q^2 + 1 - a = 0. \quad (2)$$

Substituting  $a = 2$ ,  $q = 0.16$  gives

$$\cos^2 2\sigma - 25.1 \cos 2\sigma - 158.5 = 0,$$

so

$$\cos 2\sigma = -5.2 \text{ or } +30.3. \quad (3)$$

Referring to Fig. 8 B, we see that in (3),  $\sigma = -\frac{1}{2}\pi + i\theta$  for the region in which the point (2, 0.16) lies.† Then

$$\cos(-\pi + 2i\theta) = -\cosh 2\theta = -5.2,$$

this root of (3) being chosen since the positive one is inadmissible. Now  $|\cos 2\sigma| > 1$ , so

$$\sin 2\sigma = \pm i(\cos^2 2\sigma - 1)^{\frac{1}{2}} = \pm 5.11i, \quad (4)$$

and by (14) § 4.30 we obtain

$$\mu \simeq \pm 0.4085i, \quad \text{so } \beta = 0.4085, \quad (5)$$

where the positive sign is used conventionally. Thus (1), (5) differ in the third decimal place. In § 5.20 the former result is shown to be the more accurate.

2°. *Example.* Calculate  $\beta$  for  $y'' + (6.25 - 1.6 \cos 2z)y = 0$ . Here  $a = 6.25$ ,  $q = 0.8$ , so the parametric point lies in a stable region of Figs. 8, 11, between the curves  $a_2$  and  $b_3$ . Then  $6.25^{\frac{1}{2}} = 2.5$ , so taking the fractional part, 0.5 is a rough approximation to the value of  $\beta$ . In accordance with our remarks in 1°,  $\beta < 0.5$ .

*Method 1.* From (4) § 4.74, omitting the term in  $q^6$  (for purposes of illustration)

$$2 + \beta = \left[ 6.25 - \frac{5.25 \times 0.8^2}{2 \times 5.25^2 - 0.64} - \frac{(31.25 + 7) \times 0.8^4}{32 \times 5.25^3 \times 2.25} \right]^{\frac{1}{2}}, \quad (1)$$

$$= 6.1869^{\frac{1}{2}} = 2.4873.$$

$$\text{Hence} \quad \beta = 0.4873. \quad (2)$$

*Method 2.* Using (14) § 4.30 and (2) 1°,

$$\mu \simeq (-0.4 + 0.012 + 0.0096 - 0.00122 + 0.0227) \sin 2\sigma \quad (3)$$

$$\simeq \pm 1.385i, \quad \text{so } \beta \simeq 0.385. \quad (4)$$

In this case unity is present, because (14) § 4.30 has been used outside the region stipulated in § 4.32. The value  $\beta = 0.385$  is in marked disagreement with (2), the former being in error, since  $q$  is too large for (12), (14) § 4.30 to yield accurate results. This is indicated by the fact that 0.0227 exceeds the three prior terms numerically.

3°. *Example.* Calculate  $\mu$  for the equation

$$y'' + (1 - 0.64 \cos 2z)y = 0.$$

The point  $a = 1$ ,  $q = 0.32$  lies in an unstable region of Fig. 8 between  $b_1$  and  $a_1$ . Here (2) § 4.23 does not apply, since  $a = m^2 = 1$ , so we fall back on (12), (14) § 4.30. From the former

$$\cos^2 2\sigma - 12.72 \cos 2\sigma - 1.512 = 0,$$

† As shown in § 4.60 this value of  $\sigma$  applies to (2) for the region concerned. For (1) § 4.60,  $\sigma = i\theta$ .

giving  $\cos 2\sigma = -0.115$  or  $+12.835$ . (1)

Referring to Fig. 8B, we see that  $\sigma$  is real, so  $|\cos 2\sigma| \leq 1$  and, therefore, we choose the negative root. The reality of  $\sigma$  entails  $\sin 2\sigma = \pm(1 - \cos^2 2\sigma)^{1/2}$ , so

$$\sin 2\sigma = \pm 0.9934. \quad (2)$$

By (14) § 4.30 we find that

$$\mu = \pm 0.158 \quad (\text{see Fig. 11}). \quad (3)$$

The above examples illustrate various formulae and their limitations. If  $\mu$  is real,  $|\cos 2\sigma|$  and  $|\sin 2\sigma| \leq 1$ , but if imaginary they exceed unity. Hence for equal accuracy,  $q$  in (12), (14) § 4.30 may be greater when the solution is unstable than when it is stable ( $\mu$  imaginary).

If  $\mu$  is computed using (6) § 4.91, the result is 0.16, being less accurate than (3).

**5.11. Calculation of  $\beta$  using continued fractions,  $q > 0$ .** When  $a, q$  are such that (4) § 4.74 does not give sufficient accuracy, the method below may be used. Applying the procedure in § 3.11 to (1) § 4.17 we get the infinite continued fraction [94, 134]

$$\begin{aligned} \frac{c_{2r}}{c_{2r-2}} = & \frac{-q/(2r+\beta)^2}{1-a/(2r+\beta)^2} - \frac{q^2/(2r+\beta)^2(2r+2+\beta)^2}{1-a/(2r+2+\beta)^2} - \\ & - \frac{q^2/(2r+2+\beta)^2(2r+4+\beta)^2}{1-a/(2r+4+\beta)^2} - \dots \end{aligned} \quad (1)$$

The next step is to derive an alternative continued fraction for  $c_{2r}/c_{2r-2}$ . In (1) § 4.17 we replace  $r$  by  $(r-1)$ , divide throughout by  $qc_{2r-2}$ , and obtain

$$c_{2r}/c_{2r-2} = [a - (2r-2+\beta)^2 - q(c_{2r-4}/c_{2r-2})]/q, \quad (2)$$

$$\text{so } c_{2r-2}/c_{2r} = -q/[ (2r-2+\beta)^2 - a + q(c_{2r-4}/c_{2r-2}) ] \quad (3)$$

$$= \frac{-q/(2r-2+\beta)^2}{1-a/(2r-2+\beta)^2} - \frac{q^2/(2r-2+\beta)^2(2r-4+\beta)^2}{1-a/(2r-4+\beta)^2} - \dots \quad (4)$$

But (2) may be expressed in the form

$$c_{2r}/c_{2r-2} = \{[-(2r-2+\beta)^2 + a]/q\} - (c_{2r-4}/c_{2r-2}). \quad (5)$$

Writing  $(r-1)$  for  $r$  in (4) and substituting it for the third member of (5) yields the alternative continued fraction

$$\begin{aligned} c_{2r}/c_{2r-2} = & \frac{-(2r-2+\beta)^2 + a}{q} + \frac{q/(2r-4+\beta)^2}{1-a/(2r-4+\beta)^2} - \\ & - \frac{q^2/(2r-4+\beta)^2(2r-6+\beta)^2}{1-a/(2r-6+\beta)^2} - \dots \end{aligned} \quad (6)$$

Then (1), (6) are equal for all  $r$  provided  $\beta$  has its correct value. Thus with  $r = 1$ , we get, respectively,

$$v_0 = c_2/c_0 = \frac{-q/(\beta+2)^2}{1-a/(\beta+2)^2} - \frac{q^2/(\beta+2)^2(\beta+4)^2}{1-a/(\beta+4)^2} - \frac{q^3/(\beta+4)^2(\beta+6)^2}{1-a/(\beta+6)^2} - \dots, \quad (7)$$

$$\bar{v}_0 = c_2/c_0 = \frac{a-\beta^2}{q} + \frac{q/(\beta-2)^2}{1-a/(\beta-2)^2} - \frac{q^2/(\beta-2)^2(\beta-4)^2}{1-a/(\beta-4)^2} - \dots \quad (8)$$

(7), (8) are based upon the form of solution (2) 1° § 4.70 which progresses in even orders of  $r$ . Consequently they are suited for computing  $\beta$  when  $(a, q)$  lies in a stable region between  $a_{2n}$  and  $b_{2n+1}$ . If  $(a, q)$  lies between  $a_{2n+1}$ ,  $b_{2n+2}$  the appropriate solution is (5) 1° § 4.70, so we use the recurrence relation

$$[a-(2r+1+\beta)^2]c_{2r+1} - q(c_{2r+3} + c_{2r-1}) = 0, \quad (9)$$

which is (1) § 4.17 with  $(\beta+1)$  for  $\beta$  and  $c_{2r+1}$  for  $c_{2r}$ . Making this substitution for  $\beta$  in (7), (8) gives

$$v_1 = \frac{-q/(\beta+3)^2}{1-a/(\beta+3)^2} - \frac{q^2/(\beta+3)^2(\beta+5)^2}{1-a/(\beta+5)^2} - \frac{q^3/(\beta+5)^2(\beta+7)^2}{1-a/(\beta+7)^2} - \dots, \quad (10)$$

$$\bar{v}_1 = \frac{a-(\beta+1)^2}{q} + \frac{q/(\beta-1)^2}{1-a/(\beta-1)^2} - \frac{q^2/(\beta-1)^2(\beta-3)^2}{1-a/(\beta-3)^2} - \dots \quad (11)$$

The correct value of  $\beta$  in (7), (8) or in (10), (11) is that for which  $v_0 = \bar{v}_0$ , or  $v_1 = \bar{v}_1$ ,  $0 < \beta < 1$ . In practice we aim to make  $v_0 - \bar{v}_0$ , or  $v_1 - \bar{v}_1$ , vanish to an adequate number of decimal places. Convergence of the C.F. may be considered as in § 3.14. A numerical example is given in § 5.13 et seq.

**5.12. Calculation of  $\mu$ ,  $q$  moderate and positive, solution unstable.** When the parametric point lies in an unstable region of Figs. 8, 11 between  $b_{2n+2}$  and  $a_{2n+2}$ ,  $\mu$  is real and we write  $\beta = -i\mu$  in (7), (8) § 5.11. Then  $-v_0$  and  $\bar{v}_0 - (a + \mu^2)/q$  are seen to be conjugate complex numbers. Let  $v_0 = -(x + iy)$ , and  $\bar{v}_0 - (a + \mu^2)/q = x - iy$ . When  $(v_0 - \bar{v}_0) = 0$ , the imaginary part vanishes and

$$2R(v_0) = -2x = (a + \mu^2)/q. \quad (1)$$

It is possible to satisfy this equality by evaluating  $v_0$  alone such that twice its real part is equal to  $(a + \mu^2)/q$ , i.e.

$$2x + (a + \mu^2)/q = 0. \quad (2)$$

When the parametric point lies between  $b_{2n+1}$  and  $a_{2n+1}$ ,  $\beta$  in (10), (11) § 5.11 is replaced by  $-i\mu$ . The conditions for correct  $\mu$  are

$$R(v_1) = R(\bar{v}_1) \quad \text{and} \quad I(v_1) = I(\bar{v}_1). \quad (3)$$

**5.13. Calculate  $\beta$  for  $y'' + (3 - 4 \cos 2z)y = 0$ .** Before using the formulae in § 5.11, we have to find a trial value of  $\beta$  to start the calculation. (4) § 4.74 may be used for this purpose if  $a/q$  is large enough. Here  $a/q = 1.5$  is too small, and in consequence the term in  $q^6$  is too large. An iso- $\beta\mu$  chart of the type in Fig. 11, or the tabular values corresponding thereto, may be used if available. We proceed now as follows: In Fig. 8 the point (3, 2) lies in a stable region between  $a_1$  and  $b_2$ . For  $q = 2$ , we find from Appendix 2 that  $a_1 \simeq 2.379$ ,  $b_2 \simeq 3.672$ . Referring to Fig. 12, we divide  $BA = (4 - 1)$  on the  $a$ -axis in the ratio

$$(3^{\frac{1}{2}} - 2.379^{\frac{1}{2}}) / (3.672^{\frac{1}{2}} - 2.379^{\frac{1}{2}}) = 0.508.$$

Thus  $AC = 3 \times 0.508 = 1.524$ , so at  $C$ ,  $a = 2.524$  and, therefore,  $\beta = 2.524^{\frac{1}{2}} - 1 = 0.589$ . This is our trial  $\beta$ , and we shall see later that it is in error by  $+0.00956$ ...

Since  $(a, q)$  lies between  $a_1$ ,  $b_2$  we employ (10), (11) § 5.11, and to *demonstrate* the procedure, choose a less accurate value of  $\beta$  than 0.589. We take  $\beta = 0.56$ . Neglecting components in (10) § 5.11 beyond the third, and in (11) § 5.11 beyond the fourth—the computation being merely by way of illustration—we get

$$\begin{aligned} \frac{q^2/(\beta+5)^2(\beta+7)^2}{1-a/(\beta+7)^2} &= \frac{4/5.56^2 \times 7.56^2}{1-3/7.56^2} = 0.0024, \\ \frac{q^2/(\beta+3)^2(\beta+5)^2}{1-a/(\beta+5)^2-0.0024} &= \frac{4/3.56^2 \times 5.56^2}{1-3/5.56^2-0.0024} = 0.0114, \\ \frac{-q/(\beta+3)^2}{1-a/(\beta+3)^2-0.0114} &= \frac{-2/3.56^2}{1-3/3.56^2-0.0114} = -0.209 = v_1, \quad (1) \\ \frac{q^2/(\beta-3)^2(\beta-5)^2}{1-a/(\beta-5)^2} &= \frac{4/2.44^2 \times 4.44^2}{1-3/4.44^2} = 0.0402, \\ \frac{q^2/(\beta-1)^2(\beta-3)^2}{1-a/(\beta-3)^2-0.0402} &= \frac{4/0.44^2 \times 2.44^2}{1-3/2.44^2-0.0402} = 7.64, \\ \frac{q/(\beta-1)^2}{1-a/(\beta-1)^2-7.64} &= \frac{2/0.44^2}{1-3/0.44^2-7.64} = -0.466, \\ [a-(\beta+1)^2]/q &= (3-1.56^2)/2 = 0.285, \end{aligned}$$

so

$$\bar{v}_1 = 0.285 - 0.466 = -0.181. \quad (2)$$

Since  $v_1 \neq \bar{v}_1$  in (1), (2), we now repeat the computation with  $\beta = 0.58$  and obtain  $v_1 = -0.207$ ,  $\bar{v}_1 = -0.208$ . Whether  $\beta$  should be increased or decreased to bring  $v_1$ ,  $\bar{v}_1$  closer to equality in (1), (2) may be ascertained by examining the continued fractions.

**5.14. Interpolation.** Next we use interpolation as illustrated graphically in Fig. 13 A. In this case the crossing-point is near

FIG. 13 (A), (B). Illustrating linear interpolation for  $\beta$ .

one extremity of the range of  $\beta$ , which is likely to improve the accuracy of the result. To a first approximation—a higher one not being justifiable with three decimal places—we have

$$\frac{x}{0.02-x} = \frac{0.001}{0.028}, \quad \text{so } x = 0.0007. \quad (1)$$

Hence to three decimal places

$$\beta = 0.58 - 0.0007 = 0.579_3. \quad (2)$$

Using  $\beta = 0.579_3$ , if we repeat the calculation with five component

fractions for  $v_1$ , six for  $\bar{v}_1$ , and work to nine decimal places, a more accurate result will be obtained. Thereafter the accuracy may be improved by interpolation, and so on until the desired number of decimal places is reached.

To illustrate the procedure, in Table 5 we give the results of a calculation using two values of  $\beta$  different from those employed hitherto [94].

TABLE 5

$\beta$	0.5766	0.5794	$\Delta\beta =$	0.0028	
$v_1$	-0.20726 88	-0.20683 52	$\Delta v_1 =$	0.00043 36	$v_1 - \bar{v}_1 = -0.00004 29$
$\bar{v}_1$	-0.20348 13	-0.20679 23	$\Delta \bar{v}_1 =$	-0.00331 10	$\Delta \bar{v}_1 - \Delta v_1 = -0.00374 46$

Then to a closer approximation

$$\begin{aligned}\beta &= 0.5794 + \left( \frac{v_1 - \bar{v}_1}{\Delta \bar{v}_1 - \Delta v_1} \right) \Delta\beta, \\ &= 0.57943 \ 2.\end{aligned}\quad (3)$$

Continuing the calculation we obtain the data in Table 6 [94].

TABLE 6

$\beta$	0.5794	0.57943 2	$\Delta\beta =$	$3.2 \times 10^{-5}$	
$v_1$	-0.20683 52	-0.20683 049	$\Delta v_1 =$	$4.71 \times 10^{-6}$	$v_1 - \bar{v}_1 = -3.2 \times 10^{-7}$
$\bar{v}_1$	-0.20679 23	-0.20683 017	$\Delta \bar{v}_1 =$	$-3.787 \times 10^{-5}$	$\Delta \bar{v}_1 - \Delta v_1 = -4.26 \times 10^{-5}$

To eight decimal places

$$\beta = 0.57943 \ 2 + \left( \frac{v_1 - \bar{v}_1}{\Delta \bar{v}_1 - \Delta v_1} \right) \Delta\beta = 0.57943 \ 224. \quad (4)$$

In interpolating, it will often be found that  $|\Delta \bar{v}_1 / \Delta\beta| \gg |\Delta v_1 / \Delta\beta|$  or vice versa. It is essential, therefore, to ensure that the portions of the curves between the points of interpolation are sensibly linear. A check may be made by calculating  $v_1$ ,  $\bar{v}_1$  at an equal small interval  $\delta\beta$  on each side of the crossing-point. The points so obtained should lie on the original lines.

**5.15. Trial values of  $\beta$ .** We shall now compare trial values of  $\beta$  found by the method used in §5.13, and also by (4) §4.74. The former may be crystallized in the empirical formula

$$\beta = m \left( \left[ 1 + \left( \frac{2m+1}{m^2} \right) \phi \right]^{\frac{1}{2}} - 1 \right), \quad (1)$$

where  $\phi = (a^{\dagger} - a_m^{\dagger}) / (b_{m+1}^{\dagger} - a_m^{\dagger}) < 1$ , the values of  $a_m$ ,  $b_{m+1}$  being for

the  $q$  in the differential equation. If  $[(2m+1)/m^2]\phi$  is small enough, a first approximation to (1) is

$$\beta \simeq \left(1 + \frac{1}{2m}\right)\phi. \quad (2)$$

TABLE 7. Trial values of  $\beta$  calculated from different formulae

$a$	$q$	Formula used			More accurate value of $\beta$
		$\beta$ (1)	$\beta$ (2)	$\beta$ (4) § 4.74	
3 ( $m = 1$ )	2	0.589	$m$ too small	inapplicable: see § 5.13	0.5794
6 ( $m = 2$ )	2	0.27	0.29	0.35	0.34
8 ( $m = 2$ )	3	0.67	0.79	0.72	0.70
36 ( $m = 5$ )	16	0.51	0.54	0.62	0.583

In the second, third, and fourth rows of Table 7 the superiority of (4) § 4.74 is evident, although  $a/q$  is comparatively small. If in the fourth row  $q$  were 3,  $a/q = 12$  instead of 2.25, and the accuracy would be improved appreciably. Wherever possible, the use of (4) § 4.74 is preferable to obtain the best trial value.

Although we have concentrated our attention on the evaluation of  $\beta$ , since it is needed in differential equations, the same principles may be used to calculate  $a$  if  $\beta$ ,  $q$  are assigned. First we obtain a trial  $a$  using either (6) § 2.16 or (1) § 5.15 suitably transformed, and then (if necessary) proceed with the method of continued fractions as in § 5.13 et seq. to obtain  $v_0 = \bar{v}_0$ , or  $v_1 = \bar{v}_1$ .

**5.20. Solution of equations [134].** The methods adopted may be shown most readily by a series of numerical examples. We commence with the equation

$$y'' + (2 - 0.32 \cos 2z)y = 0, \quad (1)$$

whose parametric point ( $a = 2, q = 0.16$ ) lies in a stable region of Fig. 8 between  $a_1$  and  $b_2$ . Accordingly we choose the form of solution at (4) 1° § 4.70. Substituting it into (1), equating the coefficient of  $e^{(2r+1+\beta)zi}$  to zero,  $r = -\infty$  to  $+\infty$ , and taking  $\beta = 0.409$  from § 5.10, we obtain the recurrence relation

$$[2 - (2r + 1.409)^2]c_{2r+1} - 0.16(c_{2r+3} + c_{2r-1}) = 0. \quad (2)$$

We have taken  $\beta = 0.409$  instead of the more accurate value 0.4097 to illustrate a check later on. In § 4.77 when  $r$  is large enough we showed that  $|c_{2r+2}/c_{2r}| \sim q/4(r+1)^2$ , so that after a certain  $r$  is reached the  $|c|$  decrease very rapidly. To start the computation we assume

that  $c_{2r+3}$  vanishes to the number of decimal places required in the solution. Taking  $r = 3$  in (2) and neglecting  $c_9$ , we get

$$c_{2r-1} = [2 - (2r + 1.409)^2]c_{2r+1}/0.16, \quad (3)$$

$$\begin{aligned} \text{so} \quad c_5 &= (2 - 7.409^2)6.25c_7 \\ &= -330c_7. \end{aligned} \quad (4)$$

With  $r = 2$  in (2)

$$\begin{aligned} c_3 &= -(2 - 5.409^2)6.25 \times 330c_7 - c_7 \\ &= 5.62 \times 10^4 c_7. \end{aligned} \quad (5)$$

With  $r = 1$  in (2)

$$\begin{aligned} c_1 &= (2 - 3.409^2)6.25 \times 5.62 \times 10^4 c_7 + 330c_7 \\ &= -3.38 \times 10^6 c_7. \end{aligned} \quad (6)$$

$$\text{Thus} \quad c_7 = -2.96 \times 10^{-7} c_1. \quad (7)$$

Using (7) in (4), (5) yields

$$c_3 = -1.661 \times 10^{-2} c_1, \quad (8)$$

$$c_5 = 9.77 \times 10^{-5} c_1, \quad (9)$$

$$c_7 = -2.96 \times 10^{-7} c_1. \quad (7)$$

These numerical values illustrate the rapid decrease in the  $c$  with increase in  $r$ , when  $a = 2$ ,  $q = 0.16$ .

To calculate  $c_{-2r-1}$  we use the above method, and in the present instance commence by neglecting  $c_{-9}$ . Then with  $r = -4$  and  $c_{-9} = 0$  in (2)

$$\begin{aligned} c_{-5} &= (2 - 6.591^2)6.25c_{-7} \\ &= -259c_{-7}. \end{aligned} \quad (10)$$

With  $r = -3$

$$\begin{aligned} c_{-3} &= -(2 - 4.591^2)6.25 \times 259c_{-7} - c_{-7} \\ &= 3.1 \times 10^4 c_{-7}. \end{aligned} \quad (11)$$

$$\begin{aligned} r = -2 \quad c_{-1} &= (2 - 2.591^2)6.25 \times 3.1 \times 10^4 c_{-7} + 259c_{-7} \\ &= -9.12 \times 10^5 c_{-7}. \end{aligned} \quad (12)$$

$$\begin{aligned} r = -1 \quad c_1 &= -(2 - 0.591^2)6.25 \times 9.12 \times 10^5 c_{-7} - 3.1 \times 10^4 c_{-7} \\ &= -9.44 \times 10^6 c_{-7}. \end{aligned} \quad (13)$$

$$\text{Thus} \quad c_{-7} = -1.06 \times 10^{-7} c_1, \quad (14)$$

and since  $|c_{-7}/c_{-5}| < 4 \times 10^{-3}$ , we may anticipate that

$$|c_{-9}/c_{-7}| < 4 \times 10^{-3},$$

so by (14),  $|c_{-9}| < 4 \times 10^{-10}c_1$ . Using (14) in (10)–(12) yields

$$c_{-1} = -9.12 \times 10^5 c_{-7} = 9.67 \times 10^{-2} c_1, \quad (15)$$

$$c_{-3} = 3.1 \times 10^4 c_{-7} = -3.286 \times 10^{-3} c_1, \quad (16)$$

$$c_{-5} = -259 c_{-7} = 2.72 \times 10^{-5} c_1, \quad (17)$$

$$c_{-7} = -1.06 \times 10^{-7} c_1. \quad (18)$$

*Check on  $\beta$ .* Writing  $r = 0$  in (2) gives

$$(2 - 1.409^2)c_1 = 0.16(c_3 + c_{-1}). \quad (19)$$

Using (8), (15), the two sides of (19) are

$$1.472 \times 10^{-2} c_1 \quad \text{and} \quad 1.28 \times 10^{-2} c_1, \quad \text{respectively,} \quad (20)$$

from which it follows that the value  $\beta = 0.409$  is a little too small. Now an error in the fourth decimal place in  $\beta$  causes a trifling error in  $0.16(c_3 + c_{-1})$ , so we may write

$$2 - (1 + \beta)^2 = 1.28 \times 10^{-2}, \quad (21)$$

and an improved value of  $\beta$  is then found to be

$$\beta = 0.4097, \quad (22)$$

which is in accord with (1) § 5.10.

**5.21. Solution of  $y'' + (2 - 0.32 \cos 2z)y = 0$ .** By (4) 1° § 4.70,

$$y = \sum_{r=-\infty}^{\infty} c_{2r+1} e^{(2r+1.41)zi}, \quad (1)$$

where we have taken  $\beta \simeq 0.41$ . Substituting for  $c_{2r+1}$  from § 5.20 in (1), we obtain

$$\begin{aligned} y(z) = c_1 [ & \dots - 1.06 \times 10^{-7} e^{-6.59zi} + 2.72 \times 10^{-5} e^{-4.59zi} - \\ & - 3.286 \times 10^{-3} e^{-2.59zi} + 9.67 \times 10^{-2} e^{-0.59zi} + e^{1.41zi} - \\ & - 1.661 \times 10^{-2} e^{3.41zi} + 9.77 \times 10^{-5} e^{5.41zi} - 2.96 \times 10^{-7} e^{7.41zi} + \dots ]. \end{aligned} \quad (2)$$

This form is inconvenient, so we refer to (5) 1° § 4.70. If the latter is substituted in the above differential equation, the recurrence relation (2) § 5.20 is obtained. Hence, apart from a constant multiplier,

the coefficients  $c_{2r+1}$  must be the same in both cases. Accordingly a first solution of the equation is

$$y_1(z) = \sum_{r=-\infty}^{\infty} c_{2r+1} \cos(2r+1+\beta) \quad (3)$$

$$\begin{aligned} = c_1[ & \dots - 1.06 \times 10^{-7} \cos 6.59z + 2.72 \times 10^{-5} \cos 4.59z - \\ & - 3.286 \times 10^{-3} \cos 2.59z + 9.67 \times 10^{-2} \cos 0.59z + \\ & + \cos 1.41z - 1.661 \times 10^{-2} \cos 3.41z + 9.77 \times 10^{-5} \cos 5.41z - \\ & - 2.96 \times 10^{-7} \cos 7.41z + \dots ]. \end{aligned} \quad (4)$$

The second solution is derived by writing  $\sin$  for  $\cos$  in the  $\sum$  terms in (3), but not in (4), since the terms corresponding to negative values of  $r$  would then have the wrong signs. Thus we get

$$\begin{aligned} y_2(z) = c_1[ & \dots + 1.06 \times 10^{-7} \sin 6.59z - 2.72 \times 10^{-5} \sin 4.59z + \\ & + 3.286 \times 10^{-3} \sin 2.59z - 9.67 \times 10^{-2} \sin 0.59z + \sin 1.41z - \\ & - 1.661 \times 10^{-2} \sin 3.41z + 9.77 \times 10^{-5} \sin 5.41z - \\ & - 2.96 \times 10^{-7} \sin 7.41z + \dots ]. \end{aligned} \quad (5)$$

If (2) is expressed in circular functions, (4) is the real and (5) the imaginary part, i.e. the real and imaginary parts are linearly independent solutions of the equation, which is to be expected.

The complete solution, using (4), (5), is

$$y = Ay_1 + By_2, \quad (6)$$

where  $A$ ,  $B$  are arbitrary constants, real or complex, and this defines a fundamental system. In an application,  $A$ ,  $B$  would be obtained from the initial conditions.

*Check on the solution.* (4) may be checked as in §§ 3.13, 3.16, by aid of the relationship

$$y''(0) = (2q-a)y(0) = -1.68y(0).$$

To an adequate approximation we find that each side has the value  $-1.81$ . If greater accuracy is needed,  $\beta$  should be computed as shown in § 5.13 commencing with the value  $0.4097$ . The coefficients  $c_{2r+1}$  may then be found to the same degree of accuracy as  $\beta$ , if  $r$  is increased and more significant figures used in the calculation.

**5.22. Second method of solving  $y'' + (2 - 0.32 \cos 2z)y = 0$ .** Here we use the analysis in § 4.30 and refer to § 5.10. Then  $\mu = 0.41i^\dagger$  in (5)  $1^\circ$  § 5.10 corresponds to  $\sin 2\sigma = -5.11i$ ,  $\cos 2\sigma = -5.2$ ,  $\sigma = (-\frac{1}{2}\pi + i\theta)$ . Substituting in (16), (17) § 4.30 we find that

$\dagger$  In accordance with (22) § 5.20 we have taken this approximate value of  $\beta i$ .

$s_3 = -0.02478$ ,  $c_3 = -0.00817i$ . Thus by (1), (2) § 4.30 the first solution is

$$y_1(z) = e^{0.41zi} [\sin(z-i\theta + \frac{1}{2}\pi) - 0.02478 \sin(3z-i\theta + \frac{1}{2}\pi) - 0.00817i \cos(3z-i\theta + \frac{1}{2}\pi) + \dots] \quad (1)$$

$$= e^{0.41zi} [\cos(z-i\theta) - 0.02478 \cos(3z-i\theta) + 0.00817i \sin(3z-i\theta) + \dots]. \quad (2)$$

Expressing the circular functions in exponentials, (2) becomes

$$y_1(z) = \frac{1}{2}e^{\theta} [(\cos 1.41z + i \sin 1.41z) - 1.661 \times 10^{-2}(\cos 3.41z + i \sin 3.41z) + e^{-2\theta} \{(\cos 0.59z - i \sin 0.59z) - 3.295 \times 10^{-2}(\cos 2.59z - i \sin 2.59z) + \dots\}]. \quad (3)$$

Now  $\sin 2\sigma = \sin(-\pi + 2i\theta) = -i \sinh 2\theta = -5.11i$ , so  $\theta$  is positive and it has the value 1.166. Then  $e^{-2\theta} = 9.7 \times 10^{-2}$ , and (3) becomes

$$y_1(z) = A_1 [(\cos 1.41z + i \sin 1.41z) - 1.661 \times 10^{-2}(\cos 3.41z + i \sin 3.41z) + \dots + 9.7 \times 10^{-2}(\cos 0.59z - i \sin 0.59z) - 3.2 \times 10^{-3}(\cos 2.59z - i \sin 2.59z) + \dots], \quad (4)$$

with  $A_1 = \frac{1}{2}e^{\theta}$ . Making allowance for the reduced number of terms, (4) is seen to be a linear combination of (4), (5) § 5.21. For apart from the multipliers  $A_1$ ,  $iA_1$ , the coefficients agree well enough for the purpose of illustration. Also, since the real and imaginary parts of (4) are linearly independent solutions of the equation, apart from arbitrary constants, (4) contains the complete solution given at (6) § 5.21.

Proceeding to find  $y_2(z)$ , as shown in § 4.30, we write  $-\sigma$  for  $\sigma$ . Since  $\cos 2\sigma$  is even but  $\sin 2\sigma$  is odd, we get

$$\mu = -0.41i, \quad s_3 = -0.02478, \quad c_3 = 0.00817i.$$

Thus the second solution is

$$y_2(z) = e^{-0.41zi} [\cos(z+i\theta) - 0.02478 \cos(3z+i\theta) - 0.00817i \sin(3z+i\theta) + \dots], \quad (5)$$

which is merely (2) above with the sign of  $i$  changed. It follows, therefore, that the solutions obtained herein have the forms

$$y_1(z) = A_1[f_1(z) + if_2(z)] \quad (6)$$

and

$$y_2(z) = A_1[f_1(z) - if_2(z)]. \quad (7)$$

In applications these forms will usually be inconvenient. Thus when  $\mu$  is imaginary, the forms at (4), (5) § 5.21 are preferable. They may,

of course, be derived from above, since  $f_1(z)$ ,  $f_2(z)$  are linearly independent solutions of the differential equation. Then the complete solution may be written

$$y(z) = Af_1(z) + Bf_2(z), \quad (8)$$

where  $A, B$  are arbitrary constants.

### 5.23. Relation between solutions of types § 4.13 and § 4.30.

Although in § 4.50 we demonstrated symbolically that the solutions are alike, as they must be for uniqueness, it is interesting to ascertain whether or not the two expressions for  $\bar{Z}_0$  in (11) § 4.50 yield identical numerical results. From § 5.20,  $\bar{c}_{-1} = 9.67 \times 10^{-2} \bar{c}_1$ ,† and from § 5.10,  $\sin 2\sigma = -5.11i$ ,  $\cos 2\sigma = -5.2$ . Then  $2\cos^2\sigma - 1 = -5.2$ , so  $\cos\sigma = \pm 1.449i$ . Now  $\sigma = (-\frac{1}{2}\pi + i\theta)$ ,  $\theta = 1.166$ , so  $\cos(-\frac{1}{2}\pi + i\theta) = i \sinh\theta = +1.449i$ . Also  $\sin\sigma = \sin 2\sigma/2 \cos\sigma = -1.763$ . Substituting these values in (11) § 4.50, we obtain

$$\bar{Z}_0 = -(\bar{c}_1 + \bar{c}_{-1})/\sin\sigma = \bar{c}_1 \times 1.0967/1.763 = 0.622\bar{c}_1 \quad (1)$$

$$\text{and } \bar{Z}_0 = i(\bar{c}_1 - \bar{c}_{-1})/\cos\sigma = \bar{c}_1 \times 0.9033/1.449 = 0.623\bar{c}_1. \quad (2)$$

The approximate agreement of (1), (2) is sufficient to illustrate the point in question. Here  $\bar{Z}_0$  is real, since the  $\bar{c}$  are real by virtue of the parametric point of the equation lying in a stable region of the  $(z, q)$ -plane of Fig. 11.

**5.30. Example:** Solve  $y'' + (3 - 4 \cos 2z)y = 0$ . In § 5.14 we calculated  $\beta$  for this equation to a high degree of accuracy, but for the purpose of illustration we shall take  $\beta = 0.58$ . Adopting the scheme outlined in § 5.20, we neglect  $c_{13}$  et seq. Then with  $r = 5$  in the recurrence relation

$$[3 - (2r + 1.58)^2]c_{2r+1} - 2(c_{2r+3} + c_{2r-1}) = 0, \quad (1)$$

we get

$$\begin{aligned} = 5 \quad c_9 &= \frac{1}{2}(3 - 11.58^2)c_{11} \\ &= -65.5c_{11}; \end{aligned} \quad (2)$$

$$\begin{aligned} = 4 \quad c_7 &= -\frac{1}{2}(3 - 9.58^2) \times 65.5c_{11} - c_{11} \\ &= 2.899 \times 10^3 c_{11}; \end{aligned} \quad (3)$$

$$\begin{aligned} = 3 \quad c_5 &= \frac{1}{2}(3 - 7.58^2) \times 2899c_{11} - c_9 \\ &= -7.893 \times 10^4 c_{11}; \end{aligned} \quad (4)$$

$$\begin{aligned} = 2 \quad c_3 &= -\frac{1}{2}(3 - 5.58^2) \times 78930c_{11} - c_7 \\ &= 1.102 \times 10^6 c_{11}; \end{aligned} \quad (5)$$

† To conform with the notation in § 4.50, bars have been placed above the  $c$ .

$$\begin{aligned}
 r = 1 \quad c_1 &= \frac{1}{2}(3 - 3.58^2) \times 1.102 \times 10^6 c_{11} - c_5 \\
 &= -5.331 \times 10^6 c_{11}.
 \end{aligned} \tag{6}$$

$$\text{Thus} \quad c_3 = -0.2068 c_1 \dagger \quad (-0.20683 \ 0 c_1), \tag{7}$$

$$c_5 = 0.01478 c_1 \quad (0.01474 \ 4 c_1), \tag{8}$$

$$c_7 = -0.00054 \ 3 c_1 \quad (-0.00054 \ 2 c_1), \tag{9}$$

$$c_9 = 0.00001 \ 228 c_1 \quad (0.00001 \ 2 c_1), \tag{10}$$

$$c_{11} = -0.00000 \ 01875 c_1 \quad \text{---}. \tag{11}$$

To calculate  $c_{-2r-1}$ , we commence by neglecting  $c_{-13}$  et seq.; so with

$$\begin{aligned}
 r = -6 \quad c_{-9} &= \frac{1}{2}(3 - 10.42^2) c_{-11} \\
 &= -52.7 c_{-11};
 \end{aligned} \tag{12}$$

$$\begin{aligned}
 r = -5 \quad c_{-7} &= -\frac{(3 - 8.42^2)}{2} 52.7 c_{-11} - c_{-11} \\
 &= 1.78 \times 10^3 c_{-11};
 \end{aligned} \tag{13}$$

$$\begin{aligned}
 r = -4 \quad c_{-5} &= \frac{(3 - 6.42^2)}{2} 1780 c_{-11} - c_{-9} \\
 &= -3.405 \times 10^4 c_{-11};
 \end{aligned} \tag{14}$$

$$\begin{aligned}
 r = -3 \quad c_{-3} &= -\frac{(3 - 4.42^2)}{2} 3.405 \times 10^4 c_{-11} - c_{-7} \\
 &= 2.807 \times 10^5 c_{-11};
 \end{aligned} \tag{15}$$

$$\begin{aligned}
 r = -2 \quad c_{-1} &= \frac{(3 - 2.42^2)}{2} 2.807 \times 10^5 c_{-11} - c_{-5} \\
 &= -3.674 \times 10^5 c_{-11};
 \end{aligned} \tag{16}$$

$$\begin{aligned}
 r = -1 \quad c_1 &= -\frac{(3 - 0.42^2)}{2} 3.674 \times 10^5 c_{-11} - c_{-3} \\
 &= -8 \times 10^5 c_{-11}.
 \end{aligned} \tag{17}$$

$$\text{Thus} \quad c_{-1} = 0.4592 c_1 \quad (0.45952 \ 7 c_1), \tag{18}$$

$$c_{-3} = -0.3509 c_1 \quad (-0.35134 \ 9 c_1), \tag{19}$$

$$c_{-5} = 0.04256 c_1 \quad (0.04275 \ 2 c_1), \tag{20}$$

$$c_{-7} = -0.00222 \ 5 c_1 \quad (-0.00224 \ 0 c_1), \tag{21}$$

$$c_{-9} = 0.00006 \ 6 c_1 \quad (0.00006 \ 6 c_1), \tag{22}$$

$$c_{-11} = -0.00000 \ 125 c_1 \quad \text{---}. \tag{23}$$

† The ratio  $c_3/c_1 = -0.2068$  should be equal to  $v_1$  in § 5.14. They differ in the fifth decimal place. The values in ( ) were obtained by machine using an elaborate method of computation [94].

*Check on calculation.* This may be effected by computing  $c_{-1}$  for  $r = 0$ . Then from (1)

$$\begin{aligned} c_{-1} &= \frac{(3-1.58^2)}{2} c_1 - c_3 \\ &= (0.252 + 0.2068)c_1 \\ &= 4.588 \times 10^{-1} c_1, \end{aligned} \quad (24)$$

which differs from (18) in the third decimal place. More accurate  $c$  than those we have computed are given in brackets at the r.h.s. In (18), (24),  $c_{-1}$  is slightly too small. This defect could be rectified by using a more accurate  $\beta$ , and working to six or eight significant figures.

**5.310. Solution of  $y'' + (3 - 4 \cos 2z)y = 0$ .** Since the point  $a = 3$ ,  $q = 2$  lies in a stable region between the curves  $a_1, b_2$  in Fig. 8, the preferred form of solution is

$$y_1(z) = \sum_{r=-\infty}^{\infty} c_{2r+1} \cos(2r+1+\beta)z \quad (1)$$

$$\begin{aligned} &\simeq 0.459 \cos 0.42z + \cos 1.58z - 0.351 \cos 2.42z - \\ &\quad - 0.207 \cos 3.58z + 0.043 \cos 4.42z + 0.015 \cos 5.58z - \\ &\quad - 0.002 \cos 6.42z - \dots \end{aligned} \quad (2)$$

with  $c_1 = 1$ . The second solution is (1) with  $\sin$  for  $\cos$ , so

$$\begin{aligned} y_2(z) &\simeq -0.459 \sin 0.42z + \sin 1.58z + 0.351 \sin 2.42z - \\ &\quad - 0.207 \sin 3.58z - 0.043 \sin 4.42z + 0.015 \sin 5.58z + \\ &\quad + 0.002 \sin 6.42z - \dots \end{aligned} \quad (3)$$

The complete solution with two arbitrary constants is

$$y(z) = Ay_1(z) + By_2(z). \quad (4)$$

**5.311. The Mathieu functions  $ce_{1.58}(z, 2)$ ,  $se_{1.58}(z, 2)$ .** Referring to § 4.72, we have to compute the normalizing constant

$$K = 1 / \left[ \sum_{r=-\infty}^{\infty} c_{2r+1}^2 \right]^{\frac{1}{2}}. \quad (1)$$

Using the  $c$  in § 5.30, we find that  $K \simeq 0.852/c_1$ . Now  $c_1$  in § 5.310 is unity, so by §§ 4.71, 4.72

$$ce_{1.58}(z, 2) \simeq 0.852y_1(z) \quad (2)$$

and

$$se_{1.58}(z, 2) \simeq 0.852y_2(z). \quad (3)$$

**5.32. Alternative method of calculating  $\beta$ ,  $\mu$  [134].** The method of checking  $\beta$  in § 5.20 suggests how it may be calculated. Suppose the equation to be solved is that in § 5.30. First we obtain a trial  $\beta$  as in § 5.13, say, 0.56. Then we use (1) § 5.30 with  $r = 0$ ,  $\beta$  for 0.58, and get

$$[3 - (1 + \beta)^2]c_1 = 2(c_3 + c_{-1}). \quad (1)$$

Analysis as in §§ 5.20, 5.30 leads to the values of  $c_3$ ,  $c_{-1}$  in terms of  $c_1$ . Neglecting  $c_9$ ,  $c_{-9}$  and coefficients of higher orders, we obtain

$$[3 - (1 + \beta)^2]c_1 = 2(-0.2095 + 0.468)c_1, \quad (2)$$

so

$$\beta = 0.576, \quad (3)$$

choosing the positive root. The process may now be repeated using more significant figures in the working, and commencing with, say,  $c_{15}$ ,  $c_{-15}$ . The result will be more accurate than before. Repetition may continue until the desired accuracy has been attained. It may be preferable, however, to use interpolation. From (1) with  $\beta = 0.56$  and by aid of (2), we have

$$(3 - 1.56^2)c_1 - 2(-0.2095 + 0.468)c_1 = L_1 c_1, \quad (4)$$

giving

$$L_1 = 0.0494. \quad (5)$$

Taking  $\beta = 0.58$ , we get  $c_3$ ,  $c_{-1}$  from § 5.30, and on substitution in (1) we have

$$(3 - 1.58^2)c_1 - 2(-0.2068 + 0.4592)c_1 = L_2 c_1, \quad (6)$$

so

$$L_2 = -0.0012. \quad (7)$$

Having obtained values of  $L$  on each side of zero, we interpolate and calculate  $\beta$  when  $L$  is zero. Thus (Fig. 13 B)

$$x = \frac{(0.58 - 0.56)0.0012}{0.0494 + 0.0012} \simeq 0.00047. \quad (8)$$

Hence

$$\beta \simeq 0.58 - 0.00047 = 0.5795. \quad (9)$$

This may be improved by repetition and application of procedure similar to that in § 5.14, where an accuracy to eight decimal places is achieved.

The foregoing method is applicable to the determination of  $\mu$  (real) when  $(a, q)$  lies in an unstable region of Figs. 8, 11, but the starting value of  $\mu$  would need to be assumed, unless a rough trial value could be obtained from (6), (7) § 4.91, or as in 3° § 5.10, 1° § 5.33. Also, if  $\beta$  or  $\mu$  is assigned for a given  $q$ , the value of  $a$  may be calculated.

**5.33. Example. Solve**  $y'' + (1 - 0.32 \cos 2z)y = 0$ .†

1°. From Fig. 8 we see that the point  $a = 1$ ,  $q = 0.16$  lies in an unstable region between  $b_1$  and  $a_1$ . Thus  $\sigma$ ,  $\mu$  will be real and  $|\cos 2\sigma| < 1$ . Using (2) 1° § 5.10 we obtain the approximate equation

$$\cos^2 2\sigma - 25 \cos 2\sigma - 1.5 = 0, \quad (1)$$

so

$$\begin{aligned} \cos 2\sigma &= 12.5 \pm 12.56 \\ &= -0.06 \text{ or } +25.06. \end{aligned} \quad (2)$$

Since  $|\cos 2\sigma| < 1$ , we take

$$\cos 2\sigma = -0.06,$$

so

$$\sin 2\sigma = \mp(1 - \cos^2 2\sigma)^{\frac{1}{2}} = \mp 0.9982.$$

By Fig. 8 B,  $-\frac{1}{2}\pi \leq \sigma \leq 0$ , so

$$\sigma = -46.72^\circ = -0.815 \text{ radian}. \quad (3)$$

Using (14) § 4.30 we obtain

$$\mu \simeq \pm 0.08 \quad (\text{compare (4) § 4.92}). \quad (4)$$

Also by (16), (17) § 4.30

$$s_3 \simeq -0.02, \quad c_3 \simeq -0.0012. \quad (5)$$

Substituting  $\sigma$ ,  $\mu$ , etc., into (1), (2) § 4.30 yields the first solution, namely,

$$\begin{aligned} y_1(z) \simeq e^{0.08z} [\sin(z + 0.815) - 0.02 \sin(3z + 0.815) - \\ - 0.0012 \cos(3z + 0.815) + \dots]. \end{aligned} \quad (6)$$

To derive the second independent solution we write  $-\sigma$  for  $\sigma$ . Then  $\mu$ ,  $c_3$  being odd functions of  $\sigma$ , change sign. Thus

$$\begin{aligned} y_2(z) \simeq e^{-0.08z} [\sin(z - 0.815) - 0.02 \sin(3z - 0.815) + \\ + 0.0012 \cos(3z - 0.815) + \dots]. \end{aligned} \quad (7)$$

Now  $y_1 \rightarrow \pm\infty$  as  $z \rightarrow +\infty$ , so this part of the complete solution is unstable,

$y_2 \rightarrow 0$  as  $z \rightarrow +\infty$ , so this part of the complete solution is stable.

Hence the complete solution, with arbitrary constants  $A$ ,  $B$ , namely,

$$y = Ay_1 + By_2, \quad (8)$$

is unstable and tends to  $\pm\infty$  as  $z \rightarrow +\infty$ .

† See § 4.92 for a different method of solution.

2°. We shall now obtain the solution in the form given at (3), 2° § 4.70, namely,

$$y_1(z) = e^{\mu z} \sum_{r=-\infty}^{\infty} c_{2r+1} e^{(2r+1)zi}, \quad (1)$$

using the value of  $\mu$  at (4), 1°. The recurrence formula for the  $c$  is (1), 2° § 4.750, which may be written

$$\{a + [\mu + (2r+1)i]^2\}c_{2r+1} - q(c_{2r+3} + c_{2r-1}) = 0. \quad (2)$$

Putting  $\mu = 0.08$ ,†  $a = 1$ ,  $q = 0.16$  in (2) gives

$$\{1 + [0.08 + (2r+1)i]^2\}c_{2r+1} - 0.16(c_{2r+3} + c_{2r-1}) = 0. \quad (3)$$

To illustrate the procedure in calculating the  $c$ , assume that the real and imaginary parts of  $c_7$  vanish to an adequate number of decimal places, i.e. in the computation we put  $c_7 = 0$ . Then with

$$r = 2 \quad c_3 = -5(30-i)c_5, \quad (4)$$

where  $0.08^2/0.16 = 0.04$  has been neglected in comparison with  $-150$ . With

$$r = 1 \quad c_1 = (-50+3i)c_3 - c_5$$

$$\text{and by (4)} \quad = 5(1496-140i)c_5,$$

$$\text{so} \quad c_5 = (1.325 \times 10^{-4} + 1.24 \times 10^{-5}i)c_1. \quad (5)$$

$$\text{From (4), (5)} \quad c_3 = -(1.994 \times 10^{-2} + 1.198 \times 10^{-3}i)c_1. \quad (6)$$

To calculate the  $c_{-2r+1}$ , neglect  $c_{-7}$ , and with

$$r = -3 \text{ in (3),} \quad c_{-3} = -5(30+i)c_{-5}, \quad (7)$$

$$\begin{aligned} r = -2 \quad c_{-1} &= -(50+3i)c_{-3} - c_{-5} \\ &= 5(1496+140i)c_{-5}, \end{aligned} \quad (8)$$

$$\begin{aligned} r = -1 \quad c_1 &= (0.04-i)c_{-1} - c_{-3} \\ &= 5(229.84-1489.4i)c_{-5}, \end{aligned} \quad (9)$$

the 0.04, omitted previously, being included here. Thus

$$c_{-1} = (5.95 \times 10^{-2} + 0.998i)c_1, \quad (10)$$

$$c_{-3} = -(2.38 \times 10^{-3} + 1.978 \times 10^{-2}i)c_1, \quad (11)$$

$$c_{-5} = (2.024 \times 10^{-5} + 1.313 \times 10^{-4}i)c_1. \quad (12)$$

† When  $\mu$  cannot be calculated with adequate accuracy by the method used in 1°, or by the formulae in § 4.91, the procedure outlined in either § 5.11 (continued fractions) or § 5.34 (recurrence relation) may be used. The latter is the simpler of the two. To obtain a rough indication of the order of  $\mu$  to start a computation (trial  $\mu$ ) as in § 5.34, formula (7) § 4.91 may be used beyond its normal range. Having found  $\mu$  to the required accuracy, the solution is obtained as shown in the present section. It may, if desired, be expressed in the form given in § 4.751.

As a check we shall find  $c_{-1}$  by taking  $r = 0$  in (3). Then

$$\begin{aligned} c_{-1} &= [(0.08+i)^2+1]6.25c_1-c_3 \\ &= (5.994 \times 10^{-2} + 1.001i)c_1, \end{aligned} \quad (13)$$

which differs slightly from (10). Alternatively, from (2) with  $r = 0$

$$(\mu+i)^2+1 = 0.16(c_3+c_{-1})/c_1. \quad (14)$$

Substituting for the  $c$ , on equating real and imaginary parts, we find in each case that  $\mu$  is nearly 0.08.

3°. *The solution.* Substituting the values of  $\mu$  and the  $c$  in  $y_1 = e^{\mu z} \sum c_{2r+1} e^{(2r+1)zi}$  gives the first solution:

$$\begin{aligned} y_1(z) &= c_1 e^{0.08z} [(1.06+0.998i)\cos z - (2.232+2.1i)10^{-2}\cos 3z + \\ &\quad + (1.529+1.44i)10^{-4}\cos 5z - \dots + (0.998+0.94i)\sin z - \\ &\quad - (1.86+1.752i)10^{-2}\sin 3z + (1.189+1.123i)10^{-4}\sin 5z - \dots] \end{aligned} \quad (1)$$

$$\begin{aligned} &= c_1 e^{0.08z} [1.06+0.998i][\cos z - 2.1 \times 10^{-2}\cos 3z + \\ &\quad + 1.44 \times 10^{-4}\cos 5z - \dots + 0.94\sin z - 1.75 \times 10^{-2}\sin 3z + \\ &\quad + 1.12 \times 10^{-4}\sin 5z - \dots]. \end{aligned} \quad (2)$$

The second solution is obtained by changing the sign of  $z$  in (2). The exponential becomes  $e^{-0.08z}$ , while the sine terms alter sign.

4°. *Odd and even solutions.* The solutions in 3° are neither odd nor even. Nevertheless such solutions may be constructed using linear combinations of those in 3°. Omitting external multipliers, the solutions in 3° may be written

$$e^{0.08z} [\sum \cos + \sum \sin] \quad \text{and} \quad e^{-0.08z} [\sum \cos - \sum \sin]. \quad (1)$$

By addition we get the *even* solution

$$\bar{y}_1 = 2[\cosh 0.08z \sum \cos + \sinh 0.08z \sum \sin], \quad (2)$$

and by subtraction we get the *odd* solution

$$\bar{y}_2 = 2[\sinh 0.08z \sum \cos + \cosh 0.08z \sum \sin]. \quad (3)$$

The complete solution is

$$y = A\bar{y}_1 + B\bar{y}_2, \quad (4)$$

where  $A$ ,  $B$  are arbitrary constants, determinable from the initial conditions. The utility of such solutions in practical problems is doubtful since they both tend to infinity with  $z$ .

5°. *Relationship between (6) 1° and (2) 3°.* This is expressed by  $\bar{Z}_0$  in (11) § 4.50. The two formulae for  $\bar{Z}_0$  should give the same result,

which ought to be a multiple of  $(1.06+0.998i)$  in (2)  $3^\circ$ . Then by (11) § 4.50, with  $c_1 = \bar{c}_1 = 1$ ,

$$\bar{Z}_0 = -(1.0595+0.998i)/\sin \sigma \quad \text{and} \quad \bar{Z}_0 = (0.9405i+0.998)/\cos \sigma. \quad (1)$$

Now from  $1^\circ$ ,  $\sigma = -46.72^\circ$ , so  $\sin \sigma = -0.728$  and  $\cos \sigma = 0.686$ . Substituting these into the two fractions in (1), we find that they are in good agreement, having the value

$$\begin{aligned} \bar{Z}_0 &\simeq 1.37(1.06+0.998i) \\ &= 1.99e^{43.28^\circ i}. \end{aligned} \quad (2)$$

The angle of  $\bar{Z}_0$  is the same as that of  $Z_0$  in  $3^\circ$  § 4.752, and since by § 4.751,  $\bar{Z}_0 = M_0 Z_0$ , it follows that

$$M_0 = 1.99. \quad (3)$$

Reference should be made to § 4.752, where the conjugate properties of the coefficients in  $2^\circ$  are discussed and another form of solution is given.

**5.34. Example.** Solve  $y'' - (1.25 + 2 \cos 2z)y = 0$ . From Figs. 8, 11, we see that the parametric point  $a = -1.25$ ,  $q = 1$ , lies in an unstable region below  $a_0$ , where the iso- $\mu$  curves are asymptotic to  $a_0$  as  $q \rightarrow \pm\infty$ . When  $q = 0$ ,  $\mu = ia^\dagger$ , taking the positive root, so the curvature of the iso- $\mu$  curve through the point  $(-1.25, 1)$  is less than that of  $a_0$  ( $q = 1$ ). On this basis we proceed to find a *trial*  $\mu$  to start the computation. A few assumed iso- $\mu$  curves, which may be drawn in pencil on a large version of Fig. 8'A, show that the curve through  $(-1.25, 1)$  will *probably* intersect the  $a$ -axis between  $-(0.81)^\dagger$  and  $-1$ , i.e.  $-0.9$  and  $-1$ , if  $ia^\dagger$  is plotted instead of  $a$ .<sup>†</sup> Thus our trial  $\mu$  lies between  $0.9$  and  $1$ , so we shall choose  $0.95$ .<sup>‡</sup>

The recurrence relation for the coefficients in the solution of type (1)  $2^\circ$  § 4.70 is (1)  $1^\circ$  § 4.750. Inserting  $a = -1.25$ ,  $q = 1$ ,  $\mu = 0.95$  therein, we get

$$-[1.25 + (2r - 0.95i)^2]c_{2r} - (c_{2r+2} + c_{2r-2}) = 0. \quad (1)$$

Let  $r = 3$ , neglect  $c_8$ , and (1) gives (using a 10-inch slide-rule as we are merely demonstrating the procedure)

$$c_4 = -[1.25 + (6 - 0.95i)^2]c_6 = -36.35(1 - 0.314i)c_6. \quad (2)$$

<sup>†</sup> When  $a > 0$ ,  $a^\dagger$  is plotted.

<sup>‡</sup> If (4) § 4.74 is used to calculate  $\mu$ , as indicated in § 4.753, the value  $1.002$  is obtained. As shown later, this is a better value than  $0.95$ . The purpose of the above procedure, however, is to illustrate what may sometimes be done when the formula cannot be used.

$$r = 2 \quad c_2 = -[1.25 + (4 - 0.95i)^2]c_4 - c_6 = 506(1 - 0.914i)c_6. \quad (3)$$

$$r = 1 \quad c_0 = -[1.25 + (2 - 0.95i)^2]c_2 - c_4 = 3929(-0.107 + i)c_6. \quad (4)$$

Then

$$\text{from (4),} \quad c_6 = -2.52 \times 10^{-4}(0.107 + i)c_0, \quad (5)$$

$$\text{from (2), (5),} \quad c_4 = 9.53 \times 10^{-3}(0.421 + 0.966i)c_0, \quad (6)$$

$$\text{from (3), (5),} \quad c_2 = -(0.13 + 0.115i)c_0. \quad (7)$$

To check the trial  $\mu$  we put  $r = 0$  in (1), thereby obtaining

$$-[1.25 - 0.95^2]c_0 \text{ for the l.h.s.}$$

$$\text{and} \quad c_2 + c_{-2} = 2R(c_2) \text{ for the r.h.s.,} \quad (8)$$

since by § 4.750,  $c_2$  and  $c_{-2}$  are conjugate. Thus the l.h.s. is  $-0.35c_0$ , and the r.h.s. is  $-0.26c_0$ . Hence the trial  $\mu$  is too small, and a better value is found by substituting  $\mu$  for 0.95 and solving the resulting equation. By so doing we find that  $\mu \simeq 0.995$ , taking the positive root.† We now repeat the computation using  $\mu = 1$ , and obtain the following results:

$$\left. \begin{aligned} c_2 &= -(0.124 + 0.119i)c_0, \\ c_4 &= (3.20 + 8.93i)10^{-3}c_0, \\ c_6 &= -(6.23 + 248i)10^{-6}c_0. \end{aligned} \right\} \quad (9)$$

The remainder of the solution is left as an exercise for the reader. Since  $c_{2r}$  and  $c_{-2r}$  are conjugate,  $c_{-2}$ ,  $c_{-4}$ ,  $c_{-6}$  follow immediately from (9) by changing the sign of  $i$ . The *computation* of these coefficients would constitute a check. A partial check is obtained by repeating the procedure at (8). Then with  $\mu = 1$ , we get

$$-[1.25 - 1]c_0 = -0.25c_0 \text{ for the l.h.s.}$$

$$\text{and} \quad 2R(c_2) = -0.248c_0 \text{ for the r.h.s.} \quad (10)$$

Solving for  $\mu$  as before, we have

$$(a + \mu^2)c_0 = 2qR(c_2), \quad (11)$$

$$\text{so} \quad \mu^2 = -0.248 + 1.25 = 1.002$$

$$\text{and, therefore,} \quad \mu \simeq 1.001, \quad (12)$$

taking the positive root. Thus the results are accurate enough for

† This procedure should be used only when the difference between the two values of  $\mu$  is a small fraction of the trial value. When this is not so, a better trial  $\mu$  must be chosen.

the purpose of illustration. Greater accuracy may be obtained by increasing  $r$  at the beginning, e.g. take  $r = 5$ , neglect  $c_{12}$ , and work to (say) seven decimal places,† with  $\mu = 1.001$ . An improved value of  $\mu$  will follow, the computation is repeated, and interpolation then used as in § 5.32. The requisite technique is gradually acquired by practice.

**5.35. Solutions with  $q < 0$ .** In the solutions with  $q$  positive write  $(\frac{1}{2}\pi - z)$  for  $z$ . In the case of unstable solutions like (2), 3° § 5.33, the constant multiplier  $e^{\pm i\pi\mu}$  may be omitted.

**5.40. Solutions of  $y'' + (a \mp 2q \sin 2z)y = 0$ .** If in

$$y'' + (a - 2q \cos 2z)y = 0$$

we write  $(\frac{1}{2}\pi \mp z)$  for  $z$ , it takes the form of the first equation. Hence if  $q$  is positive, the solutions of the equation are derived from those of  $y'' + (a - 2q \cos 2z)y = 0$  by writing  $(\frac{1}{2}\pi \mp z)$  for  $z$ .

**5.41. Solutions of  $y'' + [a - 2q \cos(2z \pm \theta)]y = 0$ .** If we write  $(\frac{1}{2}\theta \pm z)$  for  $z$  in Mathieu's equation, the above form is reproduced. Accordingly for  $q$  positive, solutions of the first equation may be derived from those of the second by making this change of variable. When  $q < 0$ , write  $[\frac{1}{2}(\pi + \theta) \pm z]$  for  $z$  in the solution of Mathieu's equation.

**5.50. Example. Solve  $y'' - (3 - 4 \cosh 2z)y = 0$ .** If in § 5.30 we write  $iz$  for  $z$ , the equation there takes this form. Hence the first solution is (2) § 5.310 with  $\cosh$  written for  $\cos$ , while the second solution is (3) § 5.310 with  $\sinh$  written for  $\sin$ , the multiplier  $i$  being omitted as it is a constant.

**5.51. Example. Solve  $y'' - (3 + 4 \cosh 2z)y = 0$ .** The solutions derived by writing  $(\frac{1}{2}\pi i + z)$  for  $z$  in those of the equation in § 5.50 are unduly complicated. The simplest procedure is that given in § 4.71 for  $q$  negative, i.e. change alternate signs in § 5.50.

**5.60. Example. Solve  $y'' + 4y' + (5 - 0.32 \cos 2z)y = 0$ .** By § 4.83 we have  $\kappa = 2$ ,  $\bar{a} = 5$ ,  $a = \bar{a} - \kappa^2 = 1$ ,  $q = 0.16$ , so the auxiliary equation is

$$u'' + (1 - 0.32 \cos 2z)u = 0. \quad (1)$$

The point  $a = 1$ ,  $q = 0.16$  lies in an unstable region of Fig. 8 between

† Using a machine.

the curves  $b_1$ ,  $a_1$ , and the first solution of (1) is given by (2), 3° § 5.33. Then  $y_1(z) = e^{-2z}u_1(z)$ , so

$$y_1(z) = c_1[1.06 + 0.998i]e^{-1.92z}(\cos z - 2.1 \times 10^{-2} \cos 3z + \dots + 0.94 \sin z - 1.75 \times 10^{-2} \sin 3z + \dots). \quad (2)$$

The second solution is derived from (2), 3° § 5.33 by writing  $-z$  for  $z$  and multiplying by  $e^{-2z}$ . Thus

$$y_2(z) = c_1[1.06 + 0.998i]e^{-2.08z}(\cos z - 2.1 \times 10^{-2} \cos 3z + \dots - 0.94 \sin z + 1.75 \times 10^{-2} \sin 3z - \dots). \quad (3)$$

In (2), (3) we may write  $C = c_1[1.06 + 0.998i]$ , a constant multiplier. Both solutions tend to zero as  $z \rightarrow +\infty$ , and are, therefore, stable but non-periodic. The complete solution, with two arbitrary constants, is

$$y = Ay_1 + By_2, \quad (4)$$

and this constitutes a fundamental system.

## VI

### HILL'S EQUATION

**6.10. Form of equation.** For general purposes this may be taken as

$$\frac{d^2 y}{dz^2} + [a - 2q \psi(\omega z)] y = 0, \quad (1)$$

where  $\psi(\omega z)$  is a periodic differentiable function,<sup>†</sup> such that  $|\psi(\omega z)|_{\max} = 1$ . Usually  $\psi(\omega z)$  is even in  $z$  with

$$\int_0^{2\pi} \psi(\omega z) dz = 0.$$

Sometimes  $|\psi(\omega z)|_{\max} \neq |\psi(\omega z)|_{\min}$ , but this case is not considered herein. We assume  $a, q$  to be real. When  $\psi(\omega z) = \cos 2z$ , (1) becomes the standard Mathieu equation. In certain applications it is convenient to write (1) in the form

$$\frac{d^2 y}{dz^2} + \left( \theta_0 + 2 \sum_{r=1}^{\infty} \theta_{2r} \cos 2rz \right) y = 0, \quad (2)$$

where  $\theta_0, \theta_2, \theta_4, \dots$  are assigned parameters and  $\sum_{r=1}^{\infty} |\theta_{2r}|$  converges.

The theory in §§ 4.10–4.16 applies to (1), (2). Stability is discussed in §§ 4.14, 6.50.

**6.11. Solution of (2) § 6.10.** In accordance with § 4.13, we take a solution of the form [215]—see comments in § 6.31—

$$y_1(z) = e^{\mu z} \sum_{r=-\infty}^{\infty} c_{2r} e^{2rz i}, \quad (1)$$

where  $\mu$  may be real, imaginary, or complex. Substituting the r.h.s. of (1) into (2) § 6.10, we obtain

$$\begin{aligned} & \sum_{-\infty}^{\infty} (\mu + 2ri)^2 c_{2r} e^{2rzi} + \theta_0 \sum_{-\infty}^{\infty} c_{2r} e^{2rzi} + \theta_2 \sum_{-\infty}^{\infty} c_{2r} [e^{2(r+1)zi} + e^{2(r-1)zi}] + \\ & + \theta_4 \sum_{-\infty}^{\infty} c_{2r} [e^{2(r+2)zi} + e^{2(r-2)zi}] + \theta_6 \sum_{-\infty}^{\infty} c_{2r} [e^{2(r+3)zi} + e^{2(r-3)zi}] + \dots \end{aligned} \quad (2)$$

<sup>†</sup>  $\psi(\omega z)$  may also be periodic and finitely discontinuous (piecewise continuous), but it cannot be differentiated at its discontinuities. The saw-tooth function treated later is a case in point.

Equating the coefficient of  $e^{2riz}$  to zero,  $r = -\infty$  to  $\infty$ , we get

$$(\mu + 2ri)^2 c_{2r} + \theta_0 c_{2r} + \theta_2 (c_{2r-2} + c_{2r+2}) + \theta_4 (c_{2r-4} + c_{2r+4}) + \theta_6 (c_{2r-6} + c_{2r+6}) + \dots = 0, \quad (3)$$

or 
$$(\mu + 2ri)^2 c_{2r} + \sum_{m=-\infty}^{\infty} \theta_{2m} c_{2r+2m} = 0, \quad (4)$$

with the convention that  $\theta_{2m} = \theta_{-2m}$ . As in § 4.20 we have a set of equations, infinite in number, giving relations between the coefficients  $c_{2r}$ . Dividing (3) throughout by

$$(\mu + 2ri)^2 + \theta_0 = \theta_0 - (2r - i\mu)^2 = \phi_{2r}, \quad (5)$$

we obtain

$$c_{2r} + \frac{\theta_2}{\phi_{2r}} (c_{2r-2} + c_{2r+2}) + \frac{\theta_4}{\phi_{2r}} (c_{2r-4} + c_{2r+4}) + \dots = 0. \quad (6)$$

Giving  $r$  the values  $\dots -1, 0, 1, \dots$  in succession leads to the set of equations

$$\left. \begin{aligned} & + \frac{\theta_4}{\phi_{-2}} c_{-6} + \frac{\theta_2}{\phi_{-2}} c_{-4} + \frac{\theta_0}{\phi_{-2}} c_{-2} + \frac{\theta_2}{\phi_{-2}} c_0 + \frac{\theta_4}{\phi_{-2}} c_2 + \frac{\theta_6}{\phi_{-2}} c_4 + \dots = 0 \\ & + \frac{\theta_6}{\phi_0} c_{-6} + \frac{\theta_4}{\phi_0} c_{-4} + \frac{\theta_2}{\phi_0} c_{-2} + \frac{\theta_0}{\phi_0} c_0 + \frac{\theta_2}{\phi_0} c_2 + \frac{\theta_4}{\phi_0} c_4 + \dots = 0 \\ & + \frac{\theta_8}{\phi_2} c_{-6} + \frac{\theta_6}{\phi_2} c_{-4} + \frac{\theta_4}{\phi_2} c_{-2} + \frac{\theta_2}{\phi_2} c_0 + \frac{\theta_0}{\phi_2} c_2 + \frac{\theta_2}{\phi_2} c_4 + \dots = 0 \end{aligned} \right\} \quad (7)$$

The eliminant for the  $c$  is

$$\Delta(i\mu) = \begin{vmatrix} \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & 1 & \theta_2/\phi_{-4} & \theta_4/\phi_{-4} & \theta_6/\phi_{-4} & \theta_8/\phi_{-4} \\ \cdot & \theta_2/\phi_{-2} & 1 & \theta_2/\phi_{-2} & \theta_4/\phi_{-2} & \theta_6/\phi_{-2} \\ \cdot & \theta_4/\phi_0 & \theta_2/\phi_0 & \boxed{1} & \theta_2/\phi_0 & \theta_4/\phi_0 \\ \cdot & \theta_6/\phi_2 & \theta_4/\phi_2 & \theta_2/\phi_2 & 1 & \theta_2/\phi_2 \\ \cdot & \theta_8/\phi_4 & \theta_6/\phi_4 & \theta_4/\phi_4 & \theta_2/\phi_4 & 1 \end{vmatrix} = 0, \quad (8)$$

provided  $\theta_0 \neq (2r - i\mu)^2$ .

**6.12. Evaluation of (8) § 6.11.** Adopting the procedure in § 4.21, we can show that the determinant is absolutely convergent, provided none of  $\phi_{2r}$  vanishes. Then by an argument akin to that in §§ 4.22,

4.23, we find that [215]

$$\cos i\mu\pi = 1 - \Delta(0)[1 - \cos \pi\theta_0^\dagger] \quad (1)$$

$$\text{or} \quad \sin^2 \frac{1}{2}i\mu\pi = \Delta(0)\sin^2 \frac{1}{2}\pi\theta_0^\dagger, \quad (2)$$

where  $\Delta(0)$  is (8) § 6.11 with  $\mu = 0$ , and  $\theta_0 \neq 4r^2$ . Thus

$\Delta(0) =$

$$\begin{vmatrix} \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & 1 & \theta_2/(\theta_0-16) & \theta_4/(\theta_0-16) & \theta_6/(\theta_0-16) & \theta_8/(\theta_0-16) \\ \cdot & \theta_2/(\theta_0-4) & \boxed{1} & \theta_2/(\theta_0-4) & \theta_4/(\theta_0-4) & \theta_6/(\theta_0-4) \\ \cdot & \theta_4/\theta_0 & \theta_2/\theta_0 & \boxed{1} & \theta_2/\theta_0 & \theta_4/\theta_0 \\ \cdot & \theta_6/(\theta_0-4) & \theta_4/(\theta_0-4) & \theta_2/(\theta_0-4) & 1 & \theta_2/(\theta_0-4) \\ \cdot & \theta_8/(\theta_0-16) & \theta_6/(\theta_0-16) & \theta_4/(\theta_0-16) & \theta_2/(\theta_0-16) & 1 \end{vmatrix} \quad (3)$$

The remarks in § 4.24 on the roots of (3) § 4.20 apply equally to those of (8) § 6.11. When  $\theta_2, \theta_4, \theta_6, \dots$  are small enough, it can be shown by aid of the expansion for  $\cot x$  that

$$\Delta(0) \simeq 1 + \frac{\pi \cot \frac{1}{2}\pi\theta_0^\dagger}{4\theta_0^\dagger} \left[ \frac{\theta_2^2}{1-\theta_0} + \frac{\theta_4^2}{2^2-\theta_0} + \frac{\theta_6^2}{3^2-\theta_0} + \dots \right]. \quad (4)$$

A less accurate formula can be obtained by expanding the third-order determinant in (3) about the origin. Then if  $\theta_2, \theta_4, \dots$  are small enough

$$\Delta(0) \simeq 1 + \frac{2\theta_2^2}{\theta_0(2^2-\theta_0)} + \frac{2\theta_2^2\theta_4}{\theta_0(2^2-\theta_0)^2} - \frac{\theta_4^2}{(2^2-\theta_0)^2}. \quad (5)$$

**6.13. Example.** In the lunar perigee problem [70] which gave rise to Hill's equation, the following data were used:

$$\theta_0 = 1.15884 \ 39396 \ 0,$$

$$\theta_2 = -0.05704 \ 40187 \ 5,$$

$$\theta_4 = 0.00038 \ 32380 \ 0,$$

$$\theta_6 = -0.00000 \ 91732 \ 9.$$

Calculate the value of  $\mu$ .

1°. We shall get a first approximation using (5) § 6.12. The last two terms will be neglected, since they are of order  $\leq 10^{-7}$ . Then

$$\Delta(0) \simeq 1 + [2\theta_2^2/\theta_0(4-\theta_0)] = 1.00197, \quad (1)$$

$$\text{so} \quad [\Delta(0)]^\dagger \simeq \pm 1.00098 \ 5; \quad \text{also } \theta_0^\dagger \simeq 1.07649 \ 6. \quad (2)$$

Thus  $\sin \frac{1}{2}\pi i\mu = [\Delta(0)]^{\frac{1}{2}} \sin \frac{1}{2}\pi\theta_0^{\frac{1}{2}}$

$$\begin{aligned} &\simeq \pm 1.00098 \ 5 \cos(\tfrac{1}{2}\pi \times 0.07649 \ 6) \\ &= \pm 1.00098 \ 5 \cos 0.12016 \ 0 \\ &= \pm 1.00098 \ 5 \times 0.99278 \ 9 \\ &= \pm 0.99376 \ 7. \end{aligned} \quad (3)$$

We find that

$$\frac{1}{2}\pi i\mu = \pm 1.45909 \ 1 \quad \text{or} \quad \pm 1.68250 \ 1 \text{ radian,}$$

so  $\mu \simeq \pm 0.92888 \ 6i \quad \text{or} \quad \pm 1.07111 \ 4i, \quad (4)$

the sum being  $\pm 2i$ . Since (5) § 6.12 is not a very accurate formula, we are not justified in giving the value of  $\mu$  to more than three decimal places. Thus we take

$$\mu \simeq \pm 0.929i \quad \text{or} \quad \pm 1.071i. \quad (5)$$

2°. We shall now obtain a more accurate value of  $\mu$  using (4) § 6.12.

Then

$$\begin{array}{ll} \theta_0^{\frac{1}{2}} = & 1.07649 \ 61400 \ 8 & \frac{\pi \cot \frac{1}{2}\pi\theta_0^{\frac{1}{2}}}{4\theta_0^{\frac{1}{2}}} = -0.08809 \ 15080 \ 2 \\ \frac{1}{2}\pi\theta_0^{\frac{1}{2}} = & 1.69095 \ 61826 \ 5 \\ \cot \frac{1}{2}\pi\theta_0^{\frac{1}{2}} = & -0.12074 \ 15203 \ 9 & \theta_2^2/(1-\theta_0) = -0.02048 \ 56419 \ 7 \\ \sin \frac{1}{2}\pi\theta_0^{\frac{1}{2}} = & 0.99278 \ 94864 \ 7 & \theta_4^2/(4-\theta_0) = 0. \quad 516 \ 9 \\ [ \quad ] = & -0.02048 \ 55902 \ 7 & \theta_6^2/(9-\theta_0) = 0. \quad 1 \end{array}$$

Thus  $\Delta(0) = 1.00180 \ 46065 \ 4 \quad (1)$

and  $[\Delta(0)]^{\frac{1}{2}} = \pm 1.00090 \ 18965 \ 6. \quad (2)$

$$\begin{aligned} \sin \frac{1}{2}\pi i\mu &= [\Delta(0)]^{\frac{1}{2}} \sin \frac{1}{2}\pi\theta^{\frac{1}{2}} \\ &= \pm 0.99368 \ 48798 \ 9, \end{aligned} \quad (3)$$

so  $\mu = \pm 0.92841 \ 62006 \ 3i \quad \text{or} \quad \pm 1.07158 \ 37993 \ 7i. \quad (4)$

These values of  $\mu$  are correct to six decimal places. More accurate values may be calculated by aid of (7) § 6.30 which gives

$$\mu = \pm 0.92841 \ 67276i \quad \text{and} \quad \pm 1.07158 \ 32724i. \quad (5)$$

**6.14. Calculation of coefficients in (1) § 6.11.** Having found  $\mu$ , if  $\theta_2, \theta_4, \dots$  are small enough compared with  $\theta_0$ , an approximate solution may be obtained by neglecting all  $c$  except, say,  $c_{-4}, c_{-2}, c_0, c_2, c_4$ . In (7) § 6.11 the five equations, the central one with two immediately above and below it, each containing only  $c_{-4}, \dots, c_4$ , are solved in the usual way. A rough approximation may be got by solving the three equations within the broken-line rectangle, which include only  $c_{-2}$ ,

$c_0, c_2$ . In any case, unless  $\theta_2, \theta_4, \theta_6, \dots$  are small enough compared with  $\theta_0$ , the solution is troublesome. Additional methods are given below.

### 6.20. Transformation of Hill's equation to a Riccati type.

1°. The form of (1) § 6.10 is such that the analysis in § 4.82 may be applied provided  $\psi(\omega z)$  be written for  $\cos 2z$ . Thus the Riccati type of equation is (2) § 4.81, where  $\rho^2 = [1 - (2q/a)\psi(\omega z)]$ ; and if  $|a| \gg q > 0$ ,  $|\psi(\omega z)|_{\max} = 1$ , its solution is (13) § 4.82. In terms of  $\psi$  we have [133]

$$\begin{aligned} \frac{y_1}{y_2}(z) \simeq & \frac{\text{constant}}{[1 - (2q/a)\psi(\omega z)]^{\frac{1}{2}}} \cos \left[ a^{\frac{1}{2}} \int_0^z \left( 1 - \frac{2q}{a} \psi \right)^{\frac{1}{2}} dz + \right. \\ & \left. + \frac{\omega^2 q}{4a^{\frac{1}{2}}} \int_0^z \left\{ \psi'' + \frac{5q}{2a} \frac{\psi'^2}{[1 - (2q/a)\psi]} \right\} \frac{dz}{[1 - (2q/a)\psi]^{\frac{1}{2}}} \right]. \quad (1) \end{aligned}$$

As in § 4.82, the argument of the circular functions is periodic, the frequency of repetition being

$$\begin{aligned} f &= \frac{1}{2\pi} \frac{d}{dz} \left[ \right] \\ &= \frac{1}{2\pi} \left[ a^{\frac{1}{2}} \left( 1 - \frac{2q}{a} \psi \right)^{\frac{1}{2}} + \frac{\omega^2 q}{4a^{\frac{1}{2}}} \left\{ \frac{\psi''}{[1 - (2q/a)\psi]^{\frac{1}{2}}} + \frac{5q\psi'^2}{2a[1 - (2q/a)\psi]^{\frac{3}{2}}} \right\} \right]. \quad (2) \end{aligned}$$

Under the conditions  $|a| \gg q > 0$ ,  $|\psi(\omega z)|_{\max} = 1$ , we derive from (2) the approximation

$$f \simeq \frac{1}{2\pi} [a^{\frac{1}{2}} - qa^{-\frac{1}{2}}\psi + \frac{1}{4}\omega^2 qa^{-\frac{1}{2}}\{\psi''(1 + 3qa^{-1}\psi) + \frac{5}{2}qa^{-1}\psi'^2(1 + 5qa^{-1}\psi)\}]. \quad (3)$$

The periodicity is the reciprocal of (3).

The solution of (2) § 6.10 is obtained if in (13) § 4.82 we write  $\theta_0$  for  $a$ , and take  $\rho^2 = [1 + (2/\theta_0) \sum_{r=1}^{\infty} \theta_{2r} \cos 2rz]$ . As a first approximation, with  $\varphi(z) = \rho$  we get

$$\frac{y_1}{y_2}(z) \simeq \frac{\text{constant}}{\left[ 1 + (2/\theta_0) \sum_{r=1}^{\infty} \theta_{2r} \cos 2rz \right]^{\frac{1}{2}}} \cos \left[ \theta_0^{\frac{1}{2}} \int_0^z \left\{ 1 + (2/\theta_0) \sum_{r=1}^{\infty} \theta_{2r} \cos 2rz \right\}^{\frac{1}{2}} dz \right]. \quad (4)$$

This solution rests on the assumption that  $|\theta_0| \gg 2 \sum_{r=1}^{\infty} |\theta_{2r}|$ , and in common with (1) its boundedness implies stability, i.e. (4) does not hold for an unstable region of the  $a, q$ -plane for Hill's equation.

2°.  $2q \gg a > 0$ ,  $|\psi(\omega z)|_{\max} = 1$ . We now write (1) § 6.10 in the form

$$y'' + 2q \left[ \frac{a}{2q} - \psi(\omega z) \right] y = 0. \quad (5)$$

Substituting  $y = e^{\gamma \int \omega dz}$  with  $\gamma^2 = 2q$ , we get

$$\frac{d^2 y}{dz^2} = \gamma y \left( \frac{dw}{dz} + \gamma w^2 \right), \quad (6)$$

so from (5), (6), if  $\xi^2 = [(a/2q) - \psi]$ , (5) transforms to

$$\frac{1}{\gamma} \frac{dw}{dz} + w^2 + \xi^2 = 0. \quad (7)$$

On comparison with (2) § 4.81, the approximate solution of (5) is obtained by writing  $\gamma$  for  $\nu$ , and  $\xi$  for  $\rho$  in (13) § 4.82. Thus

$$\frac{y_1(z)}{y_2(z)} \simeq (\text{constant}) \xi^{-\frac{1}{2}} \frac{\cos \left[ (2q)^{\frac{1}{2}} \int_0^z \{ \xi - (2\xi\xi'' - 3\xi'^2)/16q\xi^3 \} dz \right]}{\sin \left[ (2q)^{\frac{1}{2}} \int_0^z \{ \xi - (2\xi\xi'' - 3\xi'^2)/16q\xi^3 \} dz \right]}. \quad (8)$$

By omitting the terms in  $\xi'$ ,  $\xi''$ , we get

$$\frac{y_1(z)}{y_2(z)} \simeq \frac{\text{constant}(2q)^{\frac{1}{2}} \cos \left[ \int_0^z \{ a - 2q\psi(\omega z) \}^{\frac{1}{2}} dz \right]}{[a - 2q\psi(\omega z)]^{\frac{1}{2}} \sin \left[ \int_0^z \{ a - 2q\psi(\omega z) \}^{\frac{1}{2}} dz \right]}. \quad (9)$$

The solution of Mathieu's equation under the above conditions is found from (9) by writing  $\cos 2z$  for  $\psi(\omega z)$ .

### 6.21. Solution of (2) § 6.10 involving Mathieu functions.

The equation may be written

$$y'' + (\theta_0 + 2\theta_2 \cos 2z)y = -2 \left[ \sum_{r=2}^{\infty} \theta_{2r} \cos 2rz \right] y. \quad (1)$$

If for a first approximation the r.h.s. of (1) may be neglected, and if  $\mu$  is imaginary, the solutions are

$$y_1(z) = \text{ce}_{m+\beta}(z, -q) \quad \text{and} \quad y_2(z) = \text{se}_{m+\beta}(z, -q), \quad (2)$$

provided  $\theta_0$  is not a characteristic number for  $\text{ce}_m$ ,  $\text{se}_m$ ,  $0 < \beta < 1$  and  $q = +\theta_2$ .† For a second approximation to the first solution we

† If  $\theta_0$  is a characteristic number, then  $\beta = 0$  or  $1$ , and with  $\theta_2 > 0$ , by Chapters II, VII, the solutions are

$$y_1 = \text{ce}_m(z, -q), \quad y_2 = \text{fe}_m(z, -q) \quad (\theta_0 = a_m),$$

$$\text{or} \quad y_1 = \text{se}_m(z, -q), \quad y_2 = \text{ge}_m(z, -q) \quad (\theta_0 = b_m).$$

With  $\theta_2 < 0$ ,  $-q$  becomes  $+q$ , and  $(-1)^s$  is absent from the second  $\Sigma$  in (3). See § 4.71.

use  $y_1(z)$  for  $y$  on the r.h.s. of (1). Then we get

$$y'' + (\theta_0 + 2\theta_2 \cos 2z)y = (-1)^{n+1} 2 \left[ \sum_{r=2}^{\infty} \theta_{2r} \cos 2rz \right] \sum_{s=-\infty}^{\infty} (-1)^s A_{2s+1}^{(m+\beta)} \left\{ \cos \left( \frac{2s+\beta}{2s+1+\beta} z \right) \right\}, \quad (3)$$

$\beta$  or  $(\beta+1)$  being used in accordance with §§ 4.70, 4.71. Taking only the important terms on the r.h.s. of (3), the equation now to be solved may be written

$$\frac{d^2 y}{dz^2} + (\theta_0 + 2\theta_2 \cos 2z)y = f(z). \quad (4)$$

**6.22. Solution of (4) § 6.21.** We write the equation in the form

$$\frac{d^2 y}{dz^2} + (a + 2q \cos 2z)y = f(z). \quad (1)$$

When  $f(z) = 0$ , we take the complete solution as the sum of two Mathieu functions  $y_1(z)$ ,  $y_2(z)$  with the arbitrary constants  $A$ ,  $B$ . Thus

$$y(z) = Ay_1 + By_2. \quad (2)$$

When the r.h.s. of (1) has the value  $f(z)$ , suppose that

$$y = Ay_1 + By_2 + A_1(z)y_1 + B_2(z)y_2, \quad (3)$$

$$0 = y_1 \frac{dA_1}{dz} + y_2 \frac{dB_2}{dz}, \quad (4)$$

where  $A_1(z)$ ,  $B_2(z)$  are variable parameters (functions of  $z$ ) added to the respective arbitrary constants in (2). Differentiating (3), we get

$$\frac{dy}{dz} = Ay'_1 + By'_2 + A_1 y'_1 + B_2 y'_2 + A'_1 y_1 + B'_2 y_2. \quad (5)$$

Using (4) in (5) gives

$$\frac{dy}{dz} = (A + A_1)y'_1 + (B + B_2)y'_2, \quad (6)$$

$$\text{so} \quad \frac{d^2 y}{dz^2} = (A + A_1)y''_1 + (B + B_2)y''_2 + A'_1 y'_1 + B'_2 y'_2. \quad (7)$$

Substituting (7) into (1) and using (3) leads to

$$(A + A_1)[y''_1 + (a + 2q \cos 2z)y_1] + (B + B_2)[y''_2 + (a + 2q \cos 2z)y_2] + A'_1 y'_1 + B'_2 y'_2 = f(z). \quad (8)$$

Now the [ ] are both zero, so (8) reduces to

$$A'_1 y'_1 + B'_2 y'_2 = f(z). \quad (9)$$

Solving (4), (9) gives

$$A'_1 = y_2 f(z) / (y_2 y'_1 - y_1 y'_2). \quad (10)$$

By § 2.191 the value of the denominator in (10) is  $-c^2$ , so

$$A'_1 = -y_2 f(z)/c^2, \quad \text{or} \quad A_1 = -\frac{1}{c^2} \int^z y_2 f(z) dz. \quad (11)$$

Also 
$$B'_2 = y_1 f(z)/c^2, \quad \text{or} \quad B_2 = \frac{1}{c^2} \int^z y_1 f(z) dz. \quad (12)$$

Substituting for  $A_1$ ,  $B_2$  from (11), (12) into (3) yields the complete solution of (1). Hence

$$y = [Ay_1 + By_2] - \frac{1}{c^2} \left[ y_1(z) \int^z y_2(u) f(u) du - y_2(z) \int^z y_1(u) f(u) du \right] \quad (13)$$

$$= \text{complementary function} + \text{particular integral}. \quad (14)$$

This solution is valid if  $-q$  be written for  $q$  in (1), provided  $y_1$ ,  $y_2$  are then solutions of  $y'' + (a - 2q \cos 2z)y = 0$ , and  $c^2$  is calculated therefrom. If  $(a, q)$  lies in a stable region of Fig. 8, these solutions are  $\text{ce}_{m+\beta}(z, q)$ ,  $\text{se}_{m+\beta}(z, q)$ .

When the point  $(a, q)$  in (1) lies in an unstable region of Fig. 8, so long as  $y_1$ ,  $y_2$  can be found, (13) gives the solution of (1). The method in § 4.90 for solving Mathieu's equation in terms of Mathieu functions is applicable to Hill's equation. Reference may also be made to § 10.70 et seq., where integral equations and their solution in connexion with Hill's equation are discussed.

**6.30. Solution of  $y'' + \left[ \theta_0 + 2 \sum_{r=1}^{\infty} \theta_{2r} \cos 2rz \right] y = 0$  by method of § 4.30 [81-3].** We assume a solution

$$y_1 = e^{\mu z} \phi(z, \sigma), \quad (1)$$

where

$$\begin{aligned} \mu = & \theta_2 \psi_2(\sigma) + \theta_4 \psi_4(\sigma) + \theta_6 \psi_6(\sigma) + \dots + \\ & + \theta_2^2 \xi_2(\sigma) + \theta_4^2 \xi_4(\sigma) + \dots + \\ & + \theta_2 \theta_4 \xi_{2,4}(\sigma) + \theta_2 \theta_6 \xi_{2,6}(\sigma) + \theta_4 \theta_6 \xi_{4,6}(\sigma) + \dots + \\ & + \theta_2^3 \chi_2(\sigma) + \dots + \\ & + \dots \end{aligned} \quad (2)$$

$$\begin{aligned} \phi(z, \sigma) = & \sin(z - \sigma) + \theta_2 f_2(z, \sigma) + \theta_4 f_4(z, \sigma) + \dots + \\ & + \theta_2^2 g_2(z, \sigma) + \theta_4^2 g_4(z, \sigma) + \dots + \\ & + \theta_2 \theta_4 g_{2,4}(z, \sigma) + \dots + \\ & + \theta_2^3 h_2(z, \sigma) + \dots + \\ & + \dots \quad \text{a periodic function,} \end{aligned} \quad (3)$$

$\sigma$  being found from the relation

$$\begin{aligned}\theta_0 = & 1 + \theta_2 \alpha_2(\sigma) + \theta_4 \alpha_4(\sigma) + \theta_6 \alpha_6(\sigma) + \dots + \\ & + \theta_2^2 \beta_2(\sigma) + \theta_4^2 \beta_4(\sigma) + \dots + \\ & + \theta_2 \theta_4 \beta_{2,4}(\sigma) + \dots + \\ & + \theta_2^3 \gamma_2(\sigma) + \dots\end{aligned}\quad (4)$$

Substituting (1) into the differential equation yields

$$\phi'' + 2\mu\phi' + \left[\mu^2 + \theta_0 + 2 \sum_{r=1}^{\infty} \theta_{2r} \cos 2rz\right]\phi = 0. \quad (5)$$

Inserting the series (2)–(4) into (5) and proceeding as in § 4.30 to get a periodic solution for  $\phi$ , we derive expressions for  $\theta_0$ ,  $\mu$ ,  $f_2$ ,  $g_2$ , etc. The analysis is much too extensive, however, for inclusion here, so the original memoir should be consulted. Expressions for  $\theta_0$  and  $\mu$  are given below for making a computation. Then

$$\begin{aligned}\theta_0 = & 1 - \frac{1}{4}\theta_2^2 - \frac{1}{6}\theta_4^2 - \frac{11}{192}\theta_2^2\theta_4 - \frac{13}{192}\theta_2\theta_4\theta_6 + \frac{1}{48}\theta_2^4 - \frac{893}{2 \cdot 21184}\theta_2^6 + \dots + \\ & + \cos 2\sigma \left[ \theta_2 + \frac{1}{4}\theta_2\theta_4 + \frac{1}{12}\theta_4\theta_6 - \frac{1}{64}\theta_2^3 + \frac{5}{192}\theta_2^2\theta_6 - \right. \\ & \quad \left. - \frac{1}{144}\theta_2\theta_4^2 - \frac{175}{9612}\theta_2^3\theta_4 + \frac{1}{288}\theta_2^5 + \dots \right] + \\ & + \cos 4\sigma \left[ \frac{1}{8}\theta_2^2 + \frac{5}{64}\theta_2^2\theta_4 + \frac{13}{576}\theta_2\theta_4\theta_6 - \frac{11}{512}\theta_2^4 + \frac{9181}{17 \cdot 69472}\theta_2^6 + \dots \right] + \\ & + \cos 6\sigma \left[ \frac{7}{512}\theta_2^3\theta_4 - \frac{13}{4096}\theta_2^5 + \dots \right] + \\ & + \cos 8\sigma \left[ -\frac{35}{32768}\theta_2^6 + \dots \right] + \dots\end{aligned}\quad (6)$$

$$\begin{aligned}\mu = & \sin 2\sigma \left[ \frac{1}{2}\theta_2 + \frac{1}{8}\theta_2\theta_4 + \frac{1}{24}\theta_4\theta_6 - \frac{3}{128}\theta_2^3 + \frac{5}{384}\theta_2^2\theta_6 + \right. \\ & \quad \left. + \frac{7}{288}\theta_2\theta_4^2 - \frac{211}{9216}\theta_2^3\theta_4 + \frac{137}{36864}\theta_2^5 + \dots \right] + \\ & + \sin 4\sigma \left[ \frac{1}{128}\theta_2^2\theta_4 + \frac{1}{1152}\theta_2\theta_4\theta_6 - \frac{3}{1024}\theta_2^4 + \frac{337}{4 \cdot 42368}\theta_2^6 + \dots \right] + \\ & + \sin 6\sigma \left[ \frac{5}{1024}\theta_2^3\theta_4 - \frac{9}{8192}\theta_2^5 + \dots \right] + \\ & + \sin 8\sigma \left[ -\frac{15}{65536}\theta_2^6 + \dots \right] + \dots\end{aligned}\quad (7)$$

**6.31. Calculation of  $\mu$ .** Using the numerical values of  $\theta_0, \theta_2, \dots$  given in § 6.13, we find from (6) § 6.30 that [81]

$$\begin{aligned} 1.15884 \ 39396 \ 0 &= 1 - 0.00081 \ 33804 \ 9 - 0.05704 \ 65855 \ 7 \cos 2\sigma + \\ &+ 0.00040 \ 66226 \ 27 \cos 4\sigma + 0.0^9 945 \cos 6\sigma - \\ &- 0.0^{10} 368 \cos 8\sigma. \end{aligned} \quad (1)$$

Thus

$$\begin{aligned} \cos 2\sigma &= -2.79871 \ 82492 \ 1 + 0.00712 \ 79047 \ 3 \cos 4\sigma + \\ &+ 0.0^7 165 \ 65 \cos 6\sigma - 0.0^8 64 \ 51 \cos 8\sigma. \end{aligned} \quad (2)$$

Expressing the r.h.s. of (2) in terms of  $\cos 2\sigma$  leads to the equation

$$\begin{aligned} 0.0^7 516 \ 08 \cos^4 2\sigma - 0.0^7 662 \ 60 \cos^3 2\sigma - 0.01425 \ 58603 \ 6 \cos^2 2\sigma + \\ + \cos 2\sigma + 2.80584 \ 60209 \ 7 = 0. \end{aligned} \quad (3)$$

Using six significant figures and the last three terms of (3), we obtain the first approximation  $\cos 2\sigma \simeq -2.70178$ . Then by the process of successive approximation it is found that

$$\cos 2\sigma = -2.70178 \ 48031 \ 8. \quad (4)$$

Since  $|\cos 2\sigma| > 1$ , by § 4.60,  $\sigma = -\frac{1}{2}\pi + i\alpha$ , and from four-figure tables  $\alpha = 0.8255$ , so  $\sigma = -\frac{1}{2}\pi + 0.8255i$ . Also

$$\sin 2\sigma = \mp i(\cos^2 2\sigma - 1)^{\frac{1}{2}} = \mp 2.50990 \ 86064 \ 0i, \quad (5)$$

$$\sin 4\sigma = 2 \sin 2\sigma \cos 2\sigma = \pm 13.56247i, \quad (6)$$

$$\sin 6\sigma = \sin 2\sigma(4 \cos^2 2\sigma - 1) = \mp 70.7758i, \quad (7)$$

$$\sin 8\sigma = 4 \sin 2\sigma(2 \cos^3 2\sigma - \cos 2\sigma) = \pm 368.8i. \quad (8)$$

Inserting the values of  $\theta_2, \theta_4, \theta_6$  in (7) § 6.30 we get

$$\begin{aligned} \mu &= -0.02852 \ 03942 \ 5 \sin 2\sigma - 0.0^7 212 \ 52 \sin 4\sigma + \\ &+ 0.0^9 3 \ 162 \sin 6\sigma - 0.0^{13} 26 \sin 8\sigma. \end{aligned} \quad (9)$$

Using (5)–(8) in (9) leads to the result

$$\mu = \pm 0.07158 \ 32724i. \quad (10)$$

By aid of the formulae in [81],  $f_2, f_4, g_2$ , etc., in (3) § 6.30 may be found, so the first solution in the form (1) § 6.30 is obtained. The second solution is derived therefrom by changing  $\sigma$  to  $-\sigma$  and  $+\mu$  to  $-\mu$ . Since  $\mu$  is imaginary the solution is stable, and if the number of decimal places is fixed (conventionally) it is periodic. It may of course be expressed in the form (4) 1° § 4.70 if desired. In this connexion we remark that the values of  $\mu$  in (10) differ by  $\pm i$  from those at 2° § 6.13 (up to the seventh decimal place), because in § 6.11

we assumed the form of solution at (1) 1° § 4.70. Without a stability chart for Hill's equation—like Figs. 8, 11—the particular form of solution required to keep  $\mu$  in the range  $0 < \mu < i$  is not always predictable. In the present instance, however,  $\theta_4, \theta_6$  are so small numerically compared with  $\theta_2$ , that the equation is approximately a Mathieu type. From Fig. 11 the point  $\theta_0, \theta_2$  lies in a stable region between  $a_1, b_2$ , so there would have been justification for replacing  $2r$  by  $2r+1$  in (1) § 6.11 in accordance with (4) 1° § 4.70. Moreover, an approximate value of  $\mu = i\beta$  may be calculated from (4) § 4.74. Using only three terms, we find that  $\mu \simeq \pm 0.0713i$  (10-inch slide-rule). The iso- $\beta$  curve  $\beta = 0.0713$  lying just above  $a_1$  in Fig. 11 is an approximation to that for Hill's equation with the  $\theta$  in § 6.13.

**6.40. Example.** We shall determine  $\mu$  for the equation [44]

$$\frac{d^2y}{dt^2} + 2\kappa \frac{dy}{dt} + [a' - 2q\psi(\omega t)]y = 0. \quad (1)$$

By § 4.83 the substitution  $y = e^{-\kappa t}u(t)$  leads to the equation

$$\frac{d^2u}{dt^2} + [a - 2q\psi(\omega t)]u = 0, \quad (2)$$

with  $a = (a' - \kappa^2)$ . For  $\psi(\omega t)$  we choose the saw-tooth function represented graphically in Fig. 14. It has period  $2\pi/\omega$ , and the Fourier expansion is

$$\psi(\omega t) = \frac{2}{\pi} \sum_{n=1}^{\infty} (-1)^{n-1} \frac{\sin n\omega t}{n}. \quad (3)$$

We see that  $\int_{-\pi/\omega}^{\pi/\omega} \psi(\omega t) dt = 0$ , and that  $|\psi(\omega t)|_{\min}^{\max} = 1$ . We consider the interval  $-\pi/\omega < t < \pi/\omega$ , where the function is defined to be

$$\psi(\omega t) = \omega t / \pi. \quad (4)$$

For this interval *alone*, (2) may be written

$$\frac{d^2u}{dt^2} + a \left( 1 - \frac{2q\omega}{a\pi} t \right) u = 0. \quad (5)$$

Writing  $\tau = (1 - \gamma_0 t)$ , where  $\gamma_0 = 2q\omega/a\pi$ , (5) transforms to

$$\frac{d^2u}{d\tau^2} + b^3 \tau u = 0, \quad (6)$$

with  $b^3 = a^3\pi^2/4q^2\omega^2$ . By aid of example 46, p. 38, reference [202] we find two linearly independent solutions of (6) to be

$$u_1 = \tau^{\frac{1}{2}} J_{\frac{1}{3}}(\alpha \tau^{\frac{1}{3}}) \quad \text{and} \quad u_2 = \tau^{\frac{1}{2}} Y_{\frac{1}{3}}(\alpha \tau^{\frac{1}{3}}), \quad (7)$$

where  $\alpha = \pi a^{\frac{1}{2}}/3\omega q$ . Although these solutions are valid for the interval  $-\pi/\omega < t < \pi/\omega$  only, they enable us to determine  $\mu$  by aid of (9) § 4.152. We now proceed to obtain the various components in that formula.

$$\begin{aligned}\frac{du_1}{d\tau} &= \tau^{\frac{1}{2}} \frac{d}{d\tau} (\alpha \tau^{\frac{1}{2}}) J_{\frac{1}{2}}'(\alpha \tau^{\frac{1}{2}}) + \frac{1}{2} \tau^{-\frac{1}{2}} J_{\frac{1}{2}}(\alpha \tau^{\frac{1}{2}}) \\ &= \frac{3}{2} \alpha \tau J_{\frac{1}{2}}'(\alpha \tau^{\frac{1}{2}}) + \frac{1}{2} \tau^{-\frac{1}{2}} J_{\frac{1}{2}}(\alpha \tau^{\frac{1}{2}}).\end{aligned}\quad (8)$$

FIG. 14. Saw-tooth wave form.

Using the recurrence relation

$$J_{\nu}'(z) = -\frac{\nu}{z} J_{\nu}(z) + J_{\nu-1}(z) \quad (9)$$

in (8) leads to 
$$\frac{du_1}{d\tau} = \frac{3}{2} \alpha \tau J_{-\frac{1}{2}}(\alpha \tau^{\frac{1}{2}}). \quad (10)$$

Then 
$$\frac{du_1}{dt} = \frac{du_1}{d\tau} \frac{d\tau}{dt} = -a^{\frac{1}{2}} \tau J_{-\frac{1}{2}}(\alpha \tau^{\frac{1}{2}}). \quad (11)$$

Similarly 
$$\frac{du_2(\omega t)}{dt} = -a^{\frac{1}{2}} \tau Y_{-\frac{1}{2}}(\alpha \tau^{\frac{1}{2}}). \quad (12)$$

**6.41. Values of the various functions at  $t = \mp \pi/\omega$ .** Writing  $2q/a = \gamma$  in the formulae in § 6.40, we obtain the following results:

$$u_1(\mp \pi) = (1 \pm \gamma)^{\frac{1}{2}} J_{\frac{1}{2}}[\alpha(1 \pm \gamma)^{\frac{1}{2}}], \quad u_1'(\mp \pi) = -a^{\frac{1}{2}}(1 \pm \gamma) J_{-\frac{1}{2}}[\alpha(1 \pm \gamma)^{\frac{1}{2}}]; \quad (1)$$

$$u_2(\mp \pi) = (1 \pm \gamma)^{\frac{1}{2}} Y_{\frac{1}{2}}[\alpha(1 \pm \gamma)^{\frac{1}{2}}], \quad u_2'(\mp \pi) = -a^{\frac{1}{2}}(1 \pm \gamma) Y_{-\frac{1}{2}}[\alpha(1 \pm \gamma)^{\frac{1}{2}}]. \quad (2)$$

The Wronskian for the Bessel functions of argument  $\alpha(1 \pm \gamma)^{\frac{1}{2}}$  is [202, p. 156, ex. 61 a]

$$\alpha(1 \pm \gamma)^{\frac{1}{2}}[J_{\frac{1}{2}} Y'_{\frac{1}{2}} - J'_{\frac{1}{2}} Y_{\frac{1}{2}}] = 2/\pi. \quad (3)$$

Using (9) § 6.40 for  $J'_{\frac{1}{2}}$  and  $Y'_{\frac{1}{2}}$  in (3) gives

$$\alpha(1 \pm \gamma)^{\frac{1}{2}}[J_{\frac{1}{2}} Y_{-\frac{1}{2}} - J_{-\frac{1}{2}} Y_{\frac{1}{2}}] = 2/\pi. \quad (4)$$

By (1) § 2.191,  $u_1 u'_2 - u_2 u'_1 \equiv c^2$ , the argument in this case being  $\mp \pi$ . Substituting from (1), (2) into this identity yields

$$-a^{\frac{1}{2}}(1 \pm \gamma)^{\frac{1}{2}}[J_{\frac{1}{2}} Y_{-\frac{1}{2}} - J_{-\frac{1}{2}} Y_{\frac{1}{2}}] = c^2 \quad (5)$$

and from (4), (5) it follows that

$$2c^2 = -4a^{\frac{1}{2}}/\pi\alpha. \quad (6)$$

**6.42. Evaluation of  $\mu$ .** We have now found expressions for all the components in formula (9) § 4.152. Substituting from (1), (2), (6) § 6.41 therein, and writing  $w_1 = \alpha(1 + \gamma)^{\frac{1}{2}}$ ,  $w_2 = \alpha(1 - \gamma)^{\frac{1}{2}}$ , we obtain after a little reduction

$$\begin{aligned} \cosh 2\mu\pi = & \frac{1}{2}\pi\alpha(1 - \gamma^2)^{\frac{1}{2}}\{(1 - \gamma)^{\frac{1}{2}}[J_{-\frac{1}{2}}(w_2)Y_{\frac{1}{2}}(w_1) - J_{\frac{1}{2}}(w_1)Y_{-\frac{1}{2}}(w_2)] + \\ & + (1 + \gamma)^{\frac{1}{2}}[J_{-\frac{1}{2}}(w_1)Y_{\frac{1}{2}}(w_2) - J_{\frac{1}{2}}(w_2)Y_{-\frac{1}{2}}(w_1)]\}. \end{aligned} \quad (1)$$

If the values of  $w_1$ ,  $w_2$  are large enough, (1) may be simplified by using the dominant terms in the asymptotic expansions of the Bessel functions. Then [202, pp. 160, 161]

$$J_{-\frac{1}{2}}(w) \sim \left(\frac{2}{\pi w}\right)^{\frac{1}{2}} \cos(w - \frac{1}{4}\pi + \frac{1}{8}\pi), \quad J_{\frac{1}{2}}(w) \sim \left(\frac{2}{\pi w}\right)^{\frac{1}{2}} \cos(w - \frac{1}{4}\pi - \frac{1}{8}\pi); \quad (2)$$

$$Y_{-\frac{1}{2}}(w) \sim \left(\frac{2}{\pi w}\right)^{\frac{1}{2}} \sin(w - \frac{1}{4}\pi + \frac{1}{8}\pi), \quad Y_{\frac{1}{2}}(w) \sim \left(\frac{2}{\pi w}\right)^{\frac{1}{2}} \sin(w - \frac{1}{4}\pi - \frac{1}{8}\pi); \quad (3)$$

the part omitted in each case being  $O(1/w^{\frac{3}{2}})$ . Substituting these into (1), after some reduction we find that

$$\cosh 2\mu\pi = \{\gamma/(1 - \gamma^2)^{\frac{1}{2}}[(1 + \gamma)^{\frac{1}{2}} - (1 - \gamma)^{\frac{1}{2}}]\}\cos(w_1 - w_2). \quad (4)$$

Since stability of the solutions of (1) § 6.40 depends upon the factor  $e^{(\mu - \kappa)\pi}$  (see § 4.83), this subject may be investigated using (4). The circuit of Fig. 23 D is examined in this respect in [44], which may be consulted. Stability conditions for various mechanical and electrical devices are discussed in a number of the technological papers cited on pp. 373-81, and to these the technical reader is referred.

**6.50. Stability of solutions.** In § 4.60 we discussed this question for the equation  $y'' + (a - 2q \cos 2z)y = 0$ , use being made of Fig. 8 B. It can be shown that, when  $\psi(\omega z)$  is assigned, the  $(a, q)$ -plane for the equation  $y'' + [a - 2q\psi(\omega z)]y = 0$  may be divided into stable and unstable regions after the manner of Fig. 8. The stable (unstable) regions lie between characteristic curves for solutions of integral order having period  $\pi$  and  $2\pi$ † ( $\pi$  and  $\pi$ , or  $2\pi$  and  $2\pi$ ). The stability diagram is symmetrical about the  $a$ -axis, provided  $\psi(\omega z)$  is symmetrical about the origin, and is periodic with  $\int_0^{2\pi} \psi(\omega z) dz = 0$ .

Characteristic curves for coexistent solutions of fractional order having period  $2s\pi$ ,  $s \geq 2$ , and corresponding to the iso- $\beta$  curves of Fig. 11, may be drawn in the stable regions of the plane. Here  $\mu$  is imaginary, but in the unstable regions it is either real‡ or complex, according to the form of solution assumed (see § 4.70). Solutions of period  $\pi$  or  $2\pi$  do not coexist (unless  $q = 0$ ), and the second solutions corresponding thereto are probably non-periodic (like the Mathieu case), although a proof of these statements has not been published.

The asymptotic nature of the stability diagram has been discussed at some length in reference [171], which should be consulted for information on this topic. Amongst other matters it is shown that in the region corresponding to that below curve  $a_0$  in Fig. 8 B,  $\mu$  is real and the solutions unstable—as in the Mathieu case. This arises mainly from the fact that  $|a| > 2q$  and  $a$  is negative. In the regions corresponding to those above the characteristic  $a_0$ ,

$$a \sim -2q|\psi(\omega z)|_{\max} + O(q^{\frac{1}{2}}) \quad (a, q \text{ on right of } a\text{-axis}) \quad (1)$$

$$\text{and } a \sim -2q|\psi(\omega z)|_{\min} + O(q)^{\frac{1}{2}} \quad ( \text{ , , left , , } ). \quad (2)$$

If, as contemplated hitherto,  $|\psi(\omega z)|_{\max}^{\min} = 1$ , (12) § 12.21 is reproduced.

† Provided  $\psi$  has period  $\pi$ . If  $\psi$  has period  $2\pi$ , the boundaries correspond to solutions with periods  $2\pi, 4\pi$ . Reference [82] may be consulted in connexion with stability for small values of the  $\theta$  in (2) § 6.10.

‡ In this case iso- $\mu$  curves may be plotted as in Fig. 11.

## VII

### NON-PERIODIC SECOND SOLUTIONS CORRESPONDING TO $ce_m, se_m, Ce_m, Se_m$

**7.10. Non-periodicity of solution.** If the first solution has period  $\pi$  or  $2\pi$ , it may be shown that any second linearly independent solution cannot have either period. We now illustrate this by a particular case [84]:

**THEOREM:** If  $a$  be assigned for  $ce_{2n}(z, q)$ , the odd second solution cannot have period  $\pi$  when  $q \neq 0$ .

*Proof.* Suppose the second solution is the odd function

$$\sum_{r=0}^{\infty} c_{2r+2} \sin(2r+2)z,$$

which has period  $\pi$ . By (1) §3.10 we have the recurrence formula for  $ce_{2n}(z, q)$ :

$$(a-4)A_2 - q(A_4 + 2A_0) = 0, \quad (1)$$

and if the assumed second solution is substituted in Mathieu's equation, we obtain the relation

$$(a-4)c_2 - qc_4 = 0. \quad (2)$$

Multiplying (1) by  $c_2$ , (2) by  $A_2$ , and subtracting leads to

$$A_2 c_4 - A_4 c_2 = \begin{vmatrix} A_2 & A_4 \\ c_2 & c_4 \end{vmatrix} = 2A_0 c_2. \quad (3)$$

When  $r \geq 2$  the recurrence relations are, respectively,

$$(a-4r^2)A_{2r} = q(A_{2r+2} + A_{2r-2}), \quad (4)$$

and

$$(a-4r^2)c_{2r} = q(c_{2r+2} + c_{2r-2}). \quad (5)$$

Dividing (4) by (5) yields

$$A_{2r} c_{2r+2} - A_{2r+2} c_{2r} = A_{2r-2} c_{2r} - A_{2r} c_{2r-2}, \quad (6)$$

so [84]

$$\begin{vmatrix} A_{2r} & A_{2r+2} \\ c_{2r} & c_{2r+2} \end{vmatrix} = \begin{vmatrix} A_{2r-2} & A_{2r} \\ c_{2r-2} & c_{2r} \end{vmatrix} = \dots = \begin{vmatrix} A_2 & A_4 \\ c_2 & c_4 \end{vmatrix} = 2A_0 c_2. \quad (7)$$

For convergence of the series representing each of the two solutions, we must have  $A_{2r} \rightarrow 0$ ,  $c_{2r} \rightarrow 0$  as  $r \rightarrow +\infty$ . It follows that each determinant in (7) does likewise, so  $A_0 c_2 = 0$ . But  $A_0 \neq 0$ , save in the case  $q = 0$ ,  $n > 0$ , so  $c_2 = 0$ . Hence all the  $c$  are zero, and a second solution having period  $\pi$  does not exist. The same conclusion

may be reached for a solution of period  $2\pi$ . When the period is  $2s\pi$ ,  $s \geq 2$ , it may be inferred from §§ 2.16, 4.16 that the two solutions of Mathieu's equation coexist, and have the same period. This may be established by a method similar to that used above. Since the period cannot be a sub-multiple of  $\pi$ , it follows that the second solution corresponding to  $ce_{2n}(z, q)$  is non-periodic. The cases of  $ce_{2n+1}$ ,  $se_m$  may be argued in like manner. Since  $Ce_m(z, q)$ ,  $Se_m(z, q)$  are derived from  $ce_m(z, q)$ ,  $se_m(z, q)$ , respectively, by writing  $iz$  for  $z$ , the same conclusion may be reached here. The periods are, of course,  $\pi i$  and  $2\pi i$ . It may be remarked that a general treatment of the periodicity of the solutions of Mathieu's equation is given in [150], to which reference should be made. A different approach to the non-periodicity aspect will be found in [71, 89, 126].

**7.20. Relationship between first and second solutions.** The following analysis is applicable when the first solution has period  $\pi$ ,  $2\pi$ , and the second is non-periodic. It does not hold when both solutions are periodic with period  $2s\pi$ ,  $s \geq 2$ .

Choose  $ce_{2n}(z, q)$  as the first solution with period  $\pi$ , even in  $z$ . Then we denote the second non-periodic solution, odd in  $z$ , by  $fe_{2n}(z, q)$ . If  $(\pi+z)$  be written for  $z$  in the differential equation, it is unchanged, so  $fe_{2n}(\pi+z)$  is also a solution. Thus we may write

$$fe_{2n}(\pi+z) = \gamma ce_{2n}(z) + \delta fe_{2n}(z), \quad (1)$$

where  $\gamma, \delta$  are constants, and the presence of  $q$  is presumed. Again, taking  $(\pi+z)$  for  $z$  in (1) gives

$$fe_{2n}(2\pi+z) = \gamma ce_{2n}(z) + \delta fe_{2n}(\pi+z), \quad (2)$$

since  $ce_{2n}(z)$  has period  $\pi$ .

Substituting for the last member of (2) from (1) leads to

$$fe_{2n}(2\pi+z) = \gamma(1+\delta)ce_{2n}(z) + \delta^2 fe_{2n}(z). \quad (3)$$

Replacing  $z$  in (3) by  $(z-\pi)$ , we get

$$fe_{2n}(\pi+z) = \gamma(1+\delta)ce_{2n}(z) - \delta^2 fe_{2n}(\pi-z), \quad (4)$$

the negative sign arising from  $fe_{2n}$  being odd in  $z$ . Putting  $-z$  for  $z$  in (1) and substituting in the third member of (4) leads to an alternative version of (1), namely,

$$fe_{2n}(\pi+z) = \gamma(1+\delta-\delta^2)ce_{2n}(z) + \delta^3 fe_{2n}(z). \quad (5)$$

For the identity of (1), (5) we must have

$$\gamma = \gamma(1+\delta-\delta^2) \quad \text{and} \quad \delta = \delta^3 \quad \text{simultaneously.} \quad (6)$$

Now  $fe_{2n}(z)$  is non-periodic, so by (1) neither  $\gamma$  nor  $\delta$  can vanish. Thus  $\delta = 1$ . Inserting this in (1) yields

$$fe_{2n}(\pi+z) = \gamma ce_{2n}(z) + fe_{2n}(z), \quad (7)$$

and since  $\gamma$  is independent of  $z$ , it follows that

$$fe_{2n}(\pi+z) - fe_{2n}(z) = \gamma ce_{2n}(z), \quad (8)$$

a periodic function having period  $\pi$ .† Thus  $fe_{2n}(z)$  must satisfy (8). In addition, when  $q = 0$  it must reduce to  $\sin 2nz$ , for  $ce_{2n}(z)$  then reduces to  $\cos 2nz$ , and these are two independent solutions of  $y'' + ay = 0$ ,  $a = 4n^2$ .

If  $f_{2n}(z, q)$  is a function periodic in  $z$ , with period  $\pi$ , and we write

$$fe_{2n}(z, q) = C_{2n}(q)z ce_{2n}(z, q) + f_{2n}(z, q), \quad (9)$$

(8) is satisfied provided  $\gamma = \pi C'_{2n}(q)$ . Also, if  $C_{2n}(q) \rightarrow 0$ ‡ and  $f_{2n}(z, q) \rightarrow \sin 2nz$  as  $q \rightarrow 0$ , (9) fulfils the conditions for a second non-periodic§ solution of Mathieu's equation.

**7.21. The function  $f_{2n}(z, q)$  and its normalization.** The second member of (9) § 7.20 is odd in  $z$ , so  $f_{2n}(z, q)$  must be odd in order that  $fe_{2n}(z, q)$  may also be odd.

*First normalization rule, based upon § 2.11.* We take the function

$$f_{2n}(z, q) = \sin 2nz + \sum_{r=1}^{\infty} q^r S_r(z), \quad (1)$$

where  $S_r(z)$  are odd continuous functions of  $z$ , the coefficient of  $\sin 2nz$  is unity for all  $q$ , and  $f_{2n}(z, q) \rightarrow \sin 2nz$  as  $q \rightarrow 0$ .

*Second normalization rule based upon § 2.21.* Here we take

$$f_{2n}(z, q) = \sum_{r=0}^{\infty} \tilde{f}_{2r+2}^{(2n)} \sin(2r+2)z = C_{2n}(q) \sum_{r=0}^{\infty} f_{2r+2}^{(2n)} \sin(2r+2)z, \quad (2)$$

where  $\tilde{f}_{2r+2}^{(2n)} = C_{2n}(q) f_{2r+2}^{(2n)}$ . In § 7.41 it is shown that as  $q \rightarrow 0$ ,  $\tilde{f}_{2n}^{(2n)} \rightarrow 1$  while  $\tilde{f}_{2r+2}^{(2n)} \rightarrow 0$ ,  $r \neq n-1$ . This is true if we adopt the rule that

$$C_{2n}^2(q) \sum_{r=0}^{\infty} [f_{2r+2}^{(2n)}]^2 = \sum_{r=0}^{\infty} [\tilde{f}_{2r+2}^{(2n)}]^2 = 1. \quad (3)$$

Then, as  $q \rightarrow 0$ ,  $\tilde{f}_{2n}^{(2n)} = C_{2n}(q) f_{2n}^{(2n)} \rightarrow 1$ , (4)

and since  $\tilde{f}_{2r+2}^{(2n)} \rightarrow 0$ ,  $r \neq n-1$ ,

$$f_{2n}(z, q) \rightarrow \sin 2nz \quad (5)$$

† When the order of the function is  $(2n+1)$ ,  $ce_{2n+1}$  has period  $2\pi$ . Hence  $2\pi$  must then be written for  $\pi$  throughout.

‡ As shown in § 7.31, it is convenient to make  $C_0(q) = 1$ .

§  $q \neq 0$ .

as required. Now the  $f_{2r+2}^{(2n)}$  may be calculated by the method given in § 7.53. Then taking the positive root

$$C_{2n}(q) = 1 / \left[ \sum_{r=0}^{\infty} \{f_{2r+2}^{(2n)}\}^2 \right]^{\frac{1}{2}}. \quad (6)$$

**7.22. Definitions of the second solutions.** By aid of §§ 7.20, 7.21 we define as follows:

$$fe_{2n}(z, q) = C_{2n}(q)z ce_{2n}(z, q) + f_{2n}(z, q) \quad (a_{2n}), \quad (1)$$

$$fe_{2n+1}(z, q) = C_{2n+1}(q)z ce_{2n+1}(z, q) + f_{2n+1}(z, q) \quad (a_{2n+1}), \quad (2)$$

$$ge_{2n+1}(z, q) = S_{2n+1}(q)z se_{2n+1}(z, q) + g_{2n+1}(z, q) \quad (b_{2n+1}), \quad (3)$$

$$ge_{2n+2}(z, q) = S_{2n+2}(q)z se_{2n+2}(z, q) + g_{2n+2}(z, q) \quad (b_{2n+2}). \quad (4)$$

The series for  $f_m(z, q)$ ,  $g_m(z, q)$  are given below.

Function	First normalization in § 7.21	Second normalization in § 7.21	
$f_{2n}(z, q)$	$\sin 2nz + \sum_{r=1}^{\infty} q^r S_r(z)$	$C_{2n}(q) \sum_{r=0}^{\infty} f_{2r+2}^{(2n)} \sin(2r+2)z$	(1a)
$f_{2n+1}(z, q)$	$\sin(2n+1)z + \sum_{r=1}^{\infty} q^r \bar{S}_r(z)$	$C_{2n+1}(q) \sum_{r=0}^{\infty} f_{2r+1}^{(2n+1)} \sin(2r+1)z$	(2a)
$g_{2n+1}(z, q)$	$\cos(2n+1)z + \sum_{r=1}^{\infty} q^r \bar{C}_r(z)$	$S_{2n+1}(q) \sum_{r=0}^{\infty} g_{2r+1}^{(2n+1)} \cos(2r+1)z$	(3a)
$g_{2n+2}(z, q)$	$\cos(2n+2)z + \sum_{r=1}^{\infty} q^r C_r(z)$	$S_{2n+2}(q) \sum_{r=0}^{\infty} g_{2r}^{(2n+2)} \cos 2rz$	(4a)

As  $q \rightarrow 0$ ,

$$C_m(q)f_m^{(m)} = \bar{f}_m^{(m)} \rightarrow 1, \quad C_m(q) \rightarrow 0, \quad f_m(z, q) \rightarrow \sin mz; \quad (5)$$

$$S_m(q)g_m^{(m)} = \bar{g}_m^{(m)} \rightarrow 1, \quad S_m(q) \rightarrow 0, \quad g_m(z, q) \rightarrow \cos mz. \quad (6)$$

The second normalization is merely (1) § 2.21 applied to  $f_m(z, q)$ ,  $g_m(z, q)$ , so we get

$$\begin{aligned} C_{2n}^2 \sum_{r=0}^{\infty} f_{2r+2}^2 &= C_{2n+1}^2 \sum_{r=0}^{\infty} f_{2r+1}^2 = S_{2n+1}^2 \sum_{r=0}^{\infty} g_{2r+1}^2 \\ &= S_{2n+2}^2 \left[ 2g_0^2 + \sum_{r=1}^{\infty} g_{2r}^2 \right] = 1. \end{aligned} \quad (7)$$

The  $f$ ,  $g$  are single-valued continuous functions of  $q$ .

$f_m(z, q)$ ,  $g_m(z, q)$  are periodic, having period  $\pi$ ,  $2\pi$ , according as  $m$  is even or odd. The second solution comprises a non-periodic part involving the first solution, and a periodic part with the same period as the latter. By virtue of the factor  $z$  in the first part, the functions (1)–(4) tend to  $\pm\infty$  with  $z$ . In accordance with (a) § 4.14 these solutions are unstable. Thus, if  $(a, q)$  is upon a boundary line  $a_m$ ,  $b_m$

in Figs. 8, 11, the first solution is stable, the second unstable. If  $(a, q)$  is not upon  $a_m, b_m$ , both solutions are either (a) stable,† (b) unstable in  $-\infty < z < \infty$ .

When  $q$  is positive, and  $a$  is a characteristic number for a function of integral order, the complete solution of Mathieu's equation is

$$y(z) = A ce_m(z, q) + B fe_m(z, q) \quad (a = a_m), \quad (8)$$

$$\text{or} \quad y(z) = \bar{A} se_m(z, q) + \bar{B} ge_m(z, q) \quad (a = b_m). \quad (9)$$

Either (8) or (9) constitutes a fundamental system of solutions.

**7.30. Determination of  $C_m(q), S_m(q), f_m(z, q), g_m(z, q)$  with first normalization in § 7.21.** There are at least five methods of approach, of which we select one.‡ We exemplify this by using the function

$$fe_1(z, q) = C_1(q)z ce_1(z, q) + f_1(z, q), \quad (1)$$

which corresponds to the first solution  $ce_1(z, q)$  having period  $2\pi$ .  $f_1(z, q)$  is the second member of (2a) § 7.22 with  $n = 0$ . Substituting (1) into

$$y'' + (a - 2q \cos 2z)y = 0 \quad (2)$$

we get

$$C_1(q)z[ce_1'' + (a - 2q \cos 2z)ce_1] + f_1'' + 2C_1(q)ce_1' + (a - 2q \cos 2z)f_1 = 0. \quad (3)$$

Since  $ce_1$  is a solution of (2) for  $a = a_1$ , the [ ] vanishes leaving

$$f_1'' + 2C_1(q)ce_1' + (a - 2q \cos 2z)f_1 = 0. \quad (4)$$

By hypothesis  $C_1(0) = 0$ , so we assume  $C_1(q) = \sum_{r=1}^{\infty} \alpha_r q^r$ . Substituting

this and  $f_1(z, q) = \sin z + \sum_{r=1}^{\infty} q^r \bar{S}_r(z)$  into (4), we obtain, with the aid of results in § 2.13,

$$f_1'' = -\sin z + q\bar{S}_1'' + q^2\bar{S}_2'' + q^3\bar{S}_3'' + \dots,$$

$$2C_1 ce_1' = -2 \left[ \sin z - \frac{3}{8}q \sin 3z + \frac{1}{64}q^2 \left( -3 \sin 3z + \frac{5}{3} \sin 5 \right) z - \dots \right] \times \\ \times [\alpha_1 q + \alpha_2 q^2 + \alpha_3 q^3 + \dots],$$

$$af_1 = [\sin z + q\bar{S}_1 + q^2\bar{S}_2 + \dots] \left[ 1 + q - \frac{1}{8}q^2 - \frac{1}{64}q^3 - \frac{1}{1536}q^4 + \dots \right],$$

$$-2qf_1 \cos 2z = -2q \left[ \frac{1}{2}(-\sin z + \sin 3z) + \cos 2z(q\bar{S}_1 + q^2\bar{S}_2 + q^3\bar{S}_3 + \dots) \right].$$

† The period is then  $2s\pi$ ,  $s \geq 2$ , or infinity (see § 4.71). An infinite period implies a non-periodic bounded function.

‡ Another is given in § 10.75.

Equating the coefficient of  $q^r$  to zero yields

$$q^0: \quad -\sin z + \sin z = 0, \quad \text{identically};$$

$$q: \quad \bar{S}_1'' + \bar{S}_1 - 2\alpha_1 \sin z + 2 \sin z - \sin 3z = 0.$$

Now the particular integral corresponding to  $\sin z$  is  $-\frac{1}{2}z \cos z$ , which is non-periodic.

Since  $f_1(z, q)$  is to be periodic with period  $2\pi$ , the coefficient of  $\sin z$  must vanish, so  $\alpha_1 = 1$ . Thus

$$\bar{S}_1'' + \bar{S}_1 = \sin 3z, \quad \text{giving } \bar{S}_1 = -\frac{1}{8} \sin 3z.$$

$$q^2: \quad \bar{S}_2'' + \bar{S}_2 - 2\alpha_2 \sin z + \frac{3}{4}\alpha_1 \sin 3z - \frac{1}{8} \sin z + \bar{S}_1 - 2\bar{S}_1 \cos 2z = 0,$$

$$\text{so} \quad \bar{S}_2'' + \bar{S}_2 - 2\alpha_2 \sin z + \frac{5}{8} \sin 3z + \frac{1}{8} \sin 5z = 0.$$

To avoid a non-periodic term,  $\alpha_2 = 0$ , so

$$\bar{S}_2'' + \bar{S}_2 = -\left(\frac{5}{8} \sin 3z + \frac{1}{8} \sin 5z\right),$$

$$\text{giving} \quad \bar{S}_2 = \frac{5}{64} \sin 3z + \frac{1}{192} \sin 5z.$$

$$q^3: \quad \bar{S}_3'' + \bar{S}_3 - 2\alpha_3 \sin z + \frac{\alpha_1}{32} \left(3 \sin 3z - \frac{5}{3} \sin 5z\right) - \frac{1}{64} \sin z - \frac{1}{8} \bar{S}_1 + \bar{S}_2 - 2\bar{S}_2 \cos 2z = 0,$$

so

$$\bar{S}_3'' + \bar{S}_3 - \left(2\alpha_3 + \frac{3}{32}\right) \sin z + \frac{35}{192} \sin 3z - \frac{1}{8} \sin 5z - \frac{1}{192} \sin 7z = 0.$$

As before the coefficient of  $\sin z$  must vanish, so  $\alpha_3 = -3/64$ , and

$$\bar{S}_3'' + \bar{S}_3 = -\frac{35}{192} \sin 3z + \frac{1}{8} \sin 5z + \frac{1}{192} \sin 7z,$$

$$\text{giving} \quad \bar{S}_3 = \frac{35}{1536} \sin 3z - \frac{1}{192} \sin 5z - \frac{1}{9216} \sin 7z,$$

and so on. Thus

$$C_1(q) = \sum_{r=1}^{\infty} \alpha_r q^r = q - \frac{3}{64} q^3 - \frac{3}{256} q^4 + \frac{31}{36864} q^5 + O(q^6), \quad (5)$$

and

$$f_1(z, q) = \sin z - \frac{1}{8} q \sin 3z + \frac{1}{64} q^2 \left(5 \sin 3z + \frac{1}{3} \sin 5z\right) - \frac{1}{512} q^3 \left(-\frac{35}{3} \sin 3z + \frac{8}{3} \sin 5z + \frac{1}{18} \sin 7z\right) + \dots \quad (6)$$

Finally the series representation of the second solution, corresponding to  $ce_1(z, q)$ , using the first normalization rule in § 7.21 is

$$\begin{aligned} fe_1(z, q) = & \left[ q - \frac{3}{64}q^3 - \frac{3}{256}q^4 + \frac{31}{36864}q^5 + O(q^6) \right] z ce_1(z, q) + \\ & + \left[ \sin z - \frac{1}{8}q \sin 3z + \frac{1}{64}q^2 \left( 5 \sin 3z + \frac{1}{3} \sin 5z \right) - \right. \\ & - \frac{1}{512}q^3 \left( -\frac{35}{3} \sin 3z + \frac{8}{3} \sin 5z + \frac{1}{18} \sin 7z \right) + \\ & \left. + \frac{1}{4096}q^4 \left( -\frac{17}{3} \sin 3z - \frac{343}{54} \sin 5z + \frac{61}{108} \sin 7z + \frac{1}{180} \sin 9z \right) - \dots \right]. \end{aligned} \quad (7)$$

FIG. 15. Graphs of  $fe_0(z, q)$ ,  $fe_1(z, q)$ ,  $q = 0.08$ .

By virtue of the first member on the r.h.s.  $fe_1(z, q)$  is non-periodic, unless there are values of  $q \neq 0$  for which  $C_1(q)$  vanishes. When  $q \rightarrow 0$  in (7),  $fe_1(z, q) \rightarrow \sin z$ . Also

$$fe_1(2\pi + z) - fe_1(z) = C_1(q)2\pi ce_1(z, q), \text{ a function with period } 2\pi, \quad (8)$$

so the conditions in § 7.20 are satisfied (see footnote respecting odd-order functions).

The graphs of  $fe_0(z, 0.08)$ ,  $fe_1(z, 0.08)$  are depicted in Fig. 15.

**7.31.  $C_m(q)$ ,  $S_m(q)$  for first normalization in § 7.21.** The following were obtained by procedure different from that in § 7.30 [80]:

$$fe_0 \quad C_0(q) = 1 \quad (\text{by convention}), \dagger \quad (1)$$

$$fe_1 \quad C_1(q) = q - \frac{3}{64}q^3 - \frac{3}{256}q^4 + \frac{31}{36864}q^5 + O(q^6), \quad (2)$$

† When  $a = q = 0$ , Mathieu's equation becomes  $y'' = 0$ . Thus  $y = c_1 z + c_2$ , where  $ce_0(z, 0) = 1/\sqrt{2} = c_2$ , and  $fe_0(z, 0) = C_0(q)z ce_0(z, 0) = C_0(q)z/\sqrt{2}$ . If we take  $C_0(q) = 1$ ,  $c_1 = 1/\sqrt{2}$ , and  $y = (1/\sqrt{2})(z + 1)$ .

$$fe_2 \quad C_2(q) = \frac{1}{8}q^2 - \frac{17}{1152}q^4 + O(q^6), \quad (3)$$

$$fe_3 \quad C_3(q) = \frac{1}{192}q^3 + O(q^4); \quad (4)$$

$$ge_1 \quad S_1(q) = q - \frac{3}{64}q^3 + \frac{3}{256}q^4 + \frac{31}{36864}q^5 + O(q^6), \quad (5)$$

$$ge_2 \quad S_2(q) = \frac{1}{8}q^2 + \frac{53}{6912}q^4 + O(q^6), \quad (6)$$

$$ge_3 \quad S_3(q) = \frac{1}{192}q^3 + O(q^4). \quad (7)$$

**7.32.**  $C_m(q)$ ,  $S_m(q)$  for second normalization in § 7.21, when  $q \rightarrow 0$ . By § 7.41,  $\tilde{f}_m^{(m)}$ ,  $\tilde{g}_m^{(m)}$ , the respective coefficients of  $\sin mz$ ,  $\cos mz$  in the periodic part of the series for  $fe_m(z, q)$ ,  $ge_m(z, q)$ , tend to unity as  $q \rightarrow 0$ , the other coefficients tending to zero. By (1 a)–(4 a) § 7.22 the coefficient of  $\sin mz$ ,  $\cos mz$  is unity for all  $q$ , and the remainder tend to zero with  $q$ . Hence when  $q \rightarrow 0$ ,  $C_m(q)$ ,  $S_m(q)$  for the second normalization are the limiting forms of these functions in the first normalization. Retaining only the terms of lowest order in § 7.31 gives

$$C_0(q) = 1; \quad C_1(q) = S_1(q) = q; \quad C_2(q) = S_2(q) = \frac{1}{8}q^2; \\ C_3(q) = S_3(q) = \frac{1}{192}q^3. \quad (1)$$

Accordingly these are the forms of the various functions as  $q \rightarrow 0$ . To illustrate this, the values of  $C_1(1)$  and  $C_3(1)$  were computed by the method of § 7.54 using (7) § 7.22. The results were

$$C_1(1) \simeq 0.9526, \quad (2)$$

$$C_3(1) \simeq 0.00513 \simeq 1/195. \quad (3)$$

These data indicate that  $C_1(1) \rightarrow 1$ , and  $C_3(1) \rightarrow 1/192$ .

**7.40. Recurrence relations for  $f_s^{(m)}$ ,  $g_s^{(m)}$ .** If (1) § 7.22 is substituted in series form into (2) § 7.30 and the coefficient of  $\sin(2r+2)z$  equated to zero for  $r = 0, 1, 2, \dots$ , we obtain the two recurrence relations (omitting superscripts on the  $f$ )

$$fe_{2n}(z, q): \quad (a-4)f_2 - qf_4 = 4A_2^{(2n)} \quad (1)$$

$$\text{and} \quad (a-4r^2)f_{2r} - q(f_{2r+2} + f_{2r-2}) = 4rA_{2r}^{(2n)} \quad (r \geq 2). \quad (2)$$

Similar procedure using (2)–(4) § 7.22 leads to the following:

$$fe_{2n+1}(z, q): \quad (a-1+q)f_1 - qf_3 = 2A_1^{(2n+1)}, \quad (3)$$

$$[a-(2r+1)^2]f_{2r+1} - q(f_{2r+3} + f_{2r-1}) = 2(2r+1)A_{2r+1}^{(2n+1)} \quad (r \geq 1). \quad (4)$$

$$ge_{2n+1}(z, q): \quad (a-1-q)g_1 - qg_3 = -2B_1^{(2n+1)}, \quad (5)$$

$$[a-(2r+1)^2]g_{2r+1} - q(g_{2r+3} + g_{2r-1}) = -2(2r+1)B_{2r+1}^{(2n+1)} \quad (r \geq 1). \quad (6)$$

$$ge_{2n+2}(z, q): \quad ag_0 - qg_2 = 0, \quad (7)$$

$$(a-4)g_2 - q(g_4 + 2g_0) = -4B_2^{(2n+2)}, \quad (8)$$

$$(a-4r^2)g_{2r} - q(g_{2r+2} + g_{2r-2}) = -4rB_{2r}^{(2n+2)} \quad (r \geq 2). \quad (9)$$

**7.41. Behaviour of  $\bar{f}_m, \bar{g}_m$  as  $q \rightarrow 0$ .** By § 3.32,  $A_m^{(m)} \rightarrow 1, B_m^{(m)} \rightarrow 1$ , and the remaining  $A, B \rightarrow 0$  as  $q \rightarrow 0$ . We shall now demonstrate that  $\bar{f}_m, \bar{g}_m$  have similar properties. We take the particular case of  $fe_3(z, q)$ . By §§ 2.151, 3.32, 3.33, 7.31, we have

$$a = 9 + \frac{1}{16}q^2 + \frac{1}{64}q^3 + \dots, \quad A_1^{(3)} = O(q), \quad A_3^{(3)} \rightarrow 1, \\ A_3^{(3)} = O(q), \quad C_3(q) = O(q^3), \quad \text{when } q \rightarrow 0. \quad (1)$$

Since  $f_{2r+1} = \bar{f}_{2r+1}/C_3(q)$ , (3), (4) § 7.40 may be written

$$(a-1+q)\bar{f}_1 - q\bar{f}_3 = 2C_3(q)A_1^{(3)}, \quad (2)$$

$$[a-(2r+1)^2]\bar{f}_{2r+1} - q(\bar{f}_{2r+3} + \bar{f}_{2r-1}) = 2(2r+1)C_3(q)A_{2r+1}^{(3)} \quad (r \geq 1). \quad (3)$$

Substituting for  $a, A$ , from (1) into (2) gives

$$(8+q+\frac{1}{16}q^2+\dots)\bar{f}_1 - q\bar{f}_3 = O(q^4). \quad (4)$$

Now assume that  $\bar{f}_3$  tends to a constant value as  $q \rightarrow 0$ . Then

$$\bar{f}_1 \rightarrow q\bar{f}_3/(8+q) \simeq \frac{1}{8}q(1-\frac{1}{8}q)\bar{f}_3 \rightarrow 0. \quad (5)$$

Substituting from (1) into (3) with  $r = 1, 2$ , we get

$$(\frac{1}{16}q^2 + \frac{1}{64}q^3 + \dots)\bar{f}_3 - q(\bar{f}_5 + \bar{f}_1) \simeq 6C_3(q) \quad (6)$$

$$\text{and} \quad (\frac{1}{16}q^2 + \frac{1}{64}q^3 + \dots - 16)\bar{f}_5 - q(\bar{f}_7 + \bar{f}_3) = O(q^4). \quad (7)$$

Since  $\bar{f}_3 \rightarrow$  a constant as  $q \rightarrow 0$ , it follows that  $\bar{f}_5 \rightarrow 0$ . Similarly this result may be derived for all the  $\bar{f}$  of higher order than 5. Neglecting  $\bar{f}_7$  in (7), we obtain

$$\bar{f}_5 \simeq -\frac{1}{16}q\bar{f}_3. \quad (8)$$

Substituting from (5), (8) into (6) yields

$$(\frac{1}{16}q^2 + \frac{1}{64}q^3 + \dots + \frac{1}{16}q^2 - \frac{1}{8}q^2 + \frac{1}{64}q^3)\bar{f}_3 \simeq 6C_3(q). \quad (9)$$

$$\text{Hence as } q \rightarrow 0, \quad C_3(q) \rightarrow \bar{f}_3 q^3/192. \quad (10)$$

This result is compatible with (4) § 7.31, provided  $\bar{f}_3 \rightarrow 1$  as  $q \rightarrow 0$ , so the assumption above (5) has been justified.

By similar analysis it may be shown that  $\bar{f}_m^{(m)}$  and  $\bar{g}_m^{(m)} \rightarrow 1$ , while the remaining  $\bar{f}, \bar{g} \rightarrow 0$  as  $q \rightarrow 0$ . This latter result is independent of the normalization, which must be compatible with it. The two normalizations in § 7.21 fulfil this requirement.

**7.42. Behaviour of  $f_p, g_p$ , as  $q \rightarrow 0$ .** Since  $f_{2r+1}^{(3)} = \bar{f}_{2r+1}^{(3)}/C_3(q)$ , we get by aid of (4) § 7.31

$$f_{2r+1} \rightarrow 192 \bar{f}_{2r+1}^{(3)}/q^3. \quad (1)$$

From § 7.41, when  $q \rightarrow 0$ , it may be deduced that  $\bar{f}_1, \bar{f}_5$  are  $O(q)$ ,  $\bar{f}_7 = O(q^2)$ ,  $\bar{f}_9 = O(q^3)$ , and so on. Since  $\bar{f}_3 \rightarrow 1$ , it follows from (1) that  $f_1, f_3, f_5, f_7 \rightarrow \infty$ , but this is inconsequential. Also by analysis of the type in § 7.41 it may be shown that  $C_m(q), S_m(q)$  are  $O(q^m)$ .

Hence when  $q = 0$ , if  $m = \left. \begin{matrix} 2n \\ 2n+1 \end{matrix} \right\}$  all  $f, g$  of order lower than  $m$ ,

and  $\left. \begin{matrix} 2n-1 \\ 2n \end{matrix} \right\}$  of order higher than  $m$  are infinite. Thus, including

$f_m^{(m)}, g_m^{(m)}$ , there are  $\left. \begin{matrix} 3n \\ 3n+1 \end{matrix} \right\}$  coefficients in the series which become

infinite. As before, this is inconsequential.

**7.50. Theory underlying computation of  $f_p, g_p$ .** The recurrence relation (4) § 7.40 is a complete linear difference equation of the second order. Let  $\phi_{2r+1}, \psi_{2r+1}$  be independent solutions of

$$[a - (2r+1)^2]c_{2r+1} - q(c_{2r+3} + c_{2r-1}) = 0, \quad (1)$$

and  $f_{2r+1}$  be a particular solution of (4) § 7.40. Then the general solution of the latter is

$$w_{2r+1} = f_{2r+1} + \delta \phi_{2r+1} + \epsilon \psi_{2r+1}, \quad (2)$$

where  $\delta, \epsilon$  are arbitrary constants. As shown in § 3.21, one solution of (1) tends to zero, the other to infinity as  $r \rightarrow +\infty$ . Now the  $A$  in the series for  $ce_{2n+1}(z, q)$  satisfy a relation of the form (1), and they tend to zero as  $r \rightarrow +\infty$ . Hence we may replace  $\delta \phi_{2r+1}$  by  $\theta A_{2r+1}$ ,  $\theta$  being a constant to be determined. For convergence of the series containing  $f_{2r+1}$  we must have  $f_{2r+1} \rightarrow 0$  as  $r \rightarrow +\infty$ . Then from (2)

$$w_{2r+1} = (u_{2r+1} - \epsilon \psi_{2r+1}) = f_{2r+1} + \theta A_{2r+1} \rightarrow 0 \quad \text{as } r \rightarrow +\infty. \quad (3)$$

Now choose a value of  $r = s$ , which is such that: (1)  $|A_{2r+1}|$  decreases rapidly with increase in  $r$ , (2)  $f_{2r+3}$ , say, vanishes to an adequate

number of decimal places, (3)  $|w_{2r-1}| \gg |w_{2r+3}|$ . Since  $\epsilon$  is arbitrary,† let it be such that when  $r = s$ ,  $w_{2r+1} = 0$ . Then for  $r < s$ ,

$$f_{2r+1} = w_{2r+1} - \theta A_{2r+1}^{(2n+1)}. \quad (4)$$

The value of  $\theta$  depends for given  $a, q, m$  upon the value of  $s$ . Since  $f_{2r+1}$ , expressed to a limited number of decimal places, is independent of  $s$  (if large enough), it follows that  $w_{2r+1}$  is dependent upon  $s$ . Now  $w_{2r+1} = u_{2r+1} - \epsilon \psi_{2r+1}$ , so  $\epsilon$  varies with  $s$ , as we should expect.

**7.51. Calculation of the  $w$  in § 7.50.** The  $w$  satisfy (4) § 7.40, so with  $r = s$ , we put  $w_{2s+1} = 0$ , and neglect  $w_{2s+3}$ . Using tabular values of the  $A$  [52, 95], we calculate

$$w_{2s-1} = -2(2s+1)A_{2s+1}^{(2n+1)}q^{-1}. \quad (1)$$

Also with  $r = s$  and  $(r-1)$  for  $r$ , since  $w_{2s+1} = 0$ , (4) § 7.40 gives

$$[a - (2r-1)^2]w_{2r-1} - qw_{2r-3} = 2(2r-1)A_{2r-1}^{(2n+1)}. \quad (2)$$

Since  $w_{2r-1}$  is known from (1),  $w_{2r-3}$  may be calculated from (2). Again with  $(r-2)$  for  $r$  in (4) § 7.40,  $w_{2r-5}$  may be calculated using the values of  $w_{2r-1}$ ,  $w_{2r-3}$ . Proceeding in this way we ultimately reach  $r = 1$ . Then

$$(a-9)w_3 - q(w_1 + w_5) = 6A_3^{(2n+1)}, \quad (3)$$

from which  $w_1$  may be calculated, since  $w_3, w_5$  are known.

**7.52. Determination of  $\theta$  in (4) § 7.50.** Substituting from this equation into (3) § 7.40 gives

$$(a-1+q)(w_1 - \theta A_1) - q(w_3 - \theta A_3) = 2A_1^{(2n+1)}. \quad (1)$$

$$\text{Also by (2) § 3.10} \quad qA_3 = (a-1-q)A_1. \quad (2)$$

Then from (1), (2) we obtain

$$\theta = \frac{1}{2A_1} \left[ \left( \frac{a-1+q}{q} \right) w_1 - w_3 \right] - \frac{1}{q}. \quad (3)$$

Since the values of all quantities on the r.h.s. of (3) are known from § 7.51,  $\theta$  may be calculated. Then the  $f_{2r+1}$  may be computed using (4) § 7.50.

**7.53. Calculation of the  $f_{2r+1}$  in  $fe_1(z, 8)$ .** Here  $q = 8$ ,  $a = -0.43594\ 36013\ 20_9$ . We divide (4) § 7.40 throughout by  $q$ , and substitute  $w$  for  $f$ , since  $w_{2r+1}$  is a solution. Then

$$q^{-1}[a - (2r+1)^2]w_{2r+1} - (w_{2r+3} + w_{2r-1}) = 2(2r+1)A_{2r+1}^{(1)}q^{-1}. \quad (1)$$

† Its value need not be known.

We now choose  $s$  to conform with the conditions specified below (3) §7.50. Usually several trial  $s$  will be required at this stage,

8			
9			

e.g.  $r = 8, 9$  in Table 8. With  $r = s$  in (1), we put  $w_{2s+1} = 0$ , neglect  $w_{2s+3}$ , and obtain

$$w_{2s-1} = -2(2s+1)A_{2s+1}^{(1)}q^{-1}. \quad (2)$$

Choosing  $r = s = 7$ ,  $A_{15} = -4.424_1 \times 10^{-7}$ , and (2) gives

$$w_{13} = 30 \times 4.424_1 \times 10^{-7}/8 = 1.6590_4 \times 10^{-6}. \quad (3)$$

Taking  $r = 6$  in (1),  $A_{13} = 1.24547_0 \times 10^{-5}$ , so with  $w_{15} = 0$ , by hypothesis, we get

$$-\frac{1}{8}(169.43594...)1.6590_4 \times 10^{-6} - w_{11} = \frac{25}{8} \times 1.24547_0 \times 10^{-5},$$

giving

$$w_{11} = -7.56_{15} \times 10^{-5}. \quad (4)$$

Taking  $r = 5$ ,  $A_{11} = -2.63341_9 \times 10^{-4}$ , and using  $w_{13}$ ,  $w_{11}$  in (1), we find that

$$w_9 = 1.8703_{23} \times 10^{-3}. \quad (5)$$

Proceeding in this way we obtain the values in column 6, Table 8. Using (3) § 7.52 yields

$$\theta = 1.72194\ 54961. \quad (6)$$

Next we calculate  $\theta A_{2r+1}^{(1)}$  and get column 7. Finally subtraction of the corresponding values in column 7 from those in column 6 yields the  $f_{2r+1}^{(1)}$ .

*Check that conditions in § 7.50 are satisfied.*

(1) The  $|A_{2r+1}|$  decrease rapidly with increase in  $r \geq 3$ ; see column 4, Table 8.

(2) With  $r = 7$ ,  $f_{17}$  vanishes to seven decimal places, which is adequate here.

(3) Writing  $(r+1)$  for  $r$  in (1), we get

$$[a - (2r+3)^2]w_{2r+3} - q(w_{2r+5} + w_{2r+1}) = 2(2r+3)A_{2r+3}^{(1)}. \quad (7)$$

$w_{15} = 0$ , by hypothesis, while for  $r = 7$ ,  $(2r+3)^2 \gg |a|$ , so (7) becomes approximately

$$w_{2r+3} + qw_{2r+5}/(2r+3)^2 = -2A_{2r+3}^{(1)}/(2r+3). \quad (8)$$

For  $r \geq 3$ , the data in column 6, Table 8, show that the  $w$  decrease rapidly with increase in  $r$ .† Then  $|w_{17}| > |w_{19}|$ , so in (8) the term in  $w_{2r+5}$  may be neglected. Hence

$$\begin{aligned} w_{17} &\simeq -2A_{17}/17 = -2 \times 1.22_4 \times 10^{-8}/17 \\ &\simeq -1.44 \times 10^{-9}. \end{aligned} \quad (9)$$

Thus  $|w_{13}/w_{17}| \simeq 1.659 \times 10^{-8}/1.44 \times 10^{-9} \simeq 1.15 \times 10^3$ . (10)

We have shown, therefore, that the imposed conditions are satisfied. It is of interest to remark that in a second set of calculations with  $w_{19} = 0$ ,  $\theta \simeq 1.946$ , which exceeds the value at (6) above, while for a given  $r \leq 6$ ,  $w$  exceeds that in Table 8. This is in accordance with § 7.50. The  $f_{2r+1}^{(1)}$  are in agreement to the eighth decimal place,  $r = 0$  to 7.

**7.54. Normalization.** We use the second normalization rule in § 7.21. Then from the values of  $f_{2r+1}$  in Table 8

$$\sum_{r=0}^{\infty} f_{2r+1}^2 = 0.30424\ 88_4. \quad (1)$$

Substituting in (7) § 7.22, we obtain

$$\begin{aligned} C_1(q) &= 1/(0.30424\ 88_4)^{\frac{1}{2}} \\ &= 1.81294\ 87_8. \end{aligned} \quad (2)$$

† Since  $w_{15} = 0$ , it might be preferable to say that  $|w_{2r+3}/w_{2r+1}|$  decreases rapidly with increase in  $r$ , the case of  $r = 7$  being omitted.

Multiplying the figures in column 8, Table 8, by (2) yields column 3, Table 9. Then

$$fe_1(z, 8) = (1.812\dots)z ce_1(z, 8) + \sum_{r=0}^{\infty} \bar{f}_{2r+1}^{(1)} \sin(2r+1)z. \quad (3)$$

TABLE 9

$r$	$2r+1$	$\bar{f}_{2r+1}^{(1)} = C_1(q)f_{2r+1}^{(1)}$

**7.55. Formulae for calculating  $f_{2n}$ ,  $g_{2n+1}$ ,  $g_{2n+2}$ .** These may be derived by analysis similar to that in § 7.50, and we get:

$$fe_{2n}(z, q): \quad f_{2r}^{(2n)} = w_{2r} - \theta A_{2r}^{(2n)}, \quad (1)$$

$$\theta = -\frac{1}{2A_0} \left[ \left( \frac{4-a}{q} \right) w_2 + w_4 \right] - \frac{2a}{q^2}. \quad (2)$$

$$ge_{2n+1}(z, q): \quad g_{2r+1}^{(2n+1)} = w_{2r+1} - \theta B_{2r+1}^{(2n+1)}, \quad (3)$$

$$\theta = -\frac{1}{2B_1} \left[ \left( \frac{a-1-q}{q} \right) w_1 - w_3 \right] - \frac{1}{q}. \quad (4)$$

$$ge_{2n+2}(z, q): \quad g_{2r+2}^{(2n+2)} = w_{2r+2} - \theta B_{2r+2}^{(2n+2)}, \quad (5)$$

$$\theta = \frac{1}{B_2} \left( w_2 - \frac{a}{q} w_0 \right). \quad (6)$$

The procedure in calculating the  $f$ ,  $g$  is identical in form with that in §§ 7.53, 7.54, and the normalization rule at (7) § 7.22 is used to determine  $C_m(q)$ ,  $S_m(q)$ .

**7.60. Second solutions corresponding to  $ce_m(z, -q)$ ,  $se_m(z, -q)$ .** These are derived by writing  $(\frac{1}{2}\pi - z)$  for  $z$  in (1)–(4) § 7.22. Thus, with the aid of (2)–(5) § 2.18, we obtain

$$fe_{2n}(z, -q) = (-1)^{n+1} fe_{2n}(\tfrac{1}{2}\pi - z, q) \quad (a_{2n}) \quad (1)$$

$$= -C_{2n}(q) \left[ \left( \tfrac{1}{2}\pi - z \right) ce_{2n}(z, -q) + (-1)^n \sum_{r=0}^{\infty} (-1)^r f_{2r+2}^{(2n)} \sin(2r+2)z \right], \quad (2)$$

$$\begin{aligned}
 fe_{2n+1}(z, -q) &= (-1)^n ge_{2n+1}(\tfrac{1}{2}\pi - z, q) \quad (b_{2n+1}) \\
 &= S_{2n+1}(q) \left[ (\tfrac{1}{2}\pi - z) ce_{2n+1}(z, -q) + (-1)^n \sum_{r=0}^{\infty} (-1)^r g_{2r+1}^{(2n+1)} \sin(2r+1)z \right]; \\
 &\quad (4)
 \end{aligned}$$

$$\begin{aligned}
 ge_{2n+1}(z, -q) &= (-1)^n fe_{2n+1}(\tfrac{1}{2}\pi - z, q) \quad (a_{2n+1}) \\
 &= C_{2n+1}(q) \left[ (\tfrac{1}{2}\pi - z) se_{2n+1}(z, -q) + (-1)^n \sum_{r=0}^{\infty} (-1)^r f_{2r+1}^{(2n+1)} \cos(2r+1)z \right], \\
 &\quad (6)
 \end{aligned}$$

$$\begin{aligned}
 ge_{2n+2}(z, -q) &= (-1)^n ge_{2n+2}(\tfrac{1}{2}\pi - z, q) \quad (b_{2n+2}) \\
 &= S_{2n+2}(q) \left[ (\tfrac{1}{2}\pi - z) se_{2n+2}(z, -q) + (-1)^n \sum_{r=0}^{\infty} (-1)^r g_{2r}^{(2n)} \cos 2rz \right]. \\
 &\quad (8)
 \end{aligned}$$

Then by § 7.22, when  $q \rightarrow 0$ ,

$$fe_m(z, -q) \rightarrow +\sin mz, \quad ge_m(z, -q) \rightarrow +\cos mz,$$

the multipliers  $(-1)^n$  ensuring the conventional positive signs. Since  $ce_m(z, -q) \rightarrow +\cos mz$  and  $se_m(z, -q) \rightarrow +\sin mz$ , we obtain the two solutions of  $y'' + m^2 y = 0$ , which is the degenerate form of Mathieu's equation when  $q = 0$ .

The complete solution of  $y'' + (a + 2q \cos 2z)y = 0$  for  $q$  positive, i.e.  $q$  negative in the standard form, is obtained from (8), (9) § 7.22 by writing  $-q$  for  $q$ , the characteristic numbers being those above and in § 2.18.

**7.61. Second solutions corresponding to  $Ce_m(z, q)$ ,  $Se_m(z, q)$ .** These are solutions of  $y'' - (a - 2q \cosh 2z)y = 0$ , corresponding to  $a = a_m$ ,  $a = b_m$  respectively. They are derived from (1)–(4) § 7.22 by writing  $iz$  for  $z$ . Thus for the second normalization of § 7.21, with the aid of (2)–(5) § 2.30, we get:

$$\begin{aligned}
 Fe_{2n}(z, q) &= -i fe_{2n}(zi, q) \\
 &= C_{2n}(q)z Ce_{2n}(z, q) + F_{2n}(z, q) \quad (a_{2n}), \quad (1)
 \end{aligned}$$

$$\begin{aligned}
 Fe_{2n+1}(z, q) &= -i fe_{2n+1}(zi, q) \\
 &= C_{2n+1}(q)z Ce_{2n+1}(z, q) + F_{2n+1}(z, q) \quad (a_{2n+1}); \quad (2)
 \end{aligned}$$

$$\begin{aligned}
 Ge_{2n+1}(z, q) &= ge_{2n+1}(zi, q) \\
 &= -S_{2n+1}(q)z Se_{2n+1}(z, q) + G_{2n+1}(z, q) \quad (b_{2n+1}), \quad (3)
 \end{aligned}$$

$$\begin{aligned}
 Ge_{2n+2}(z, q) &= ge_{2n+2}(zi, q) \\
 &= -S_{2n+2}(q)z Se_{2n+2}(z, q) + G_{2n+2}(z, q) \quad (b_{2n+2}). \quad (4)
 \end{aligned}$$

By writing  $iz$  for  $z$  in the third members of (1 a)–(4 a) § 7.22, we obtain

$$F_{2n}(z, q) = C_{2n}(q) \sum_{r=0}^{\infty} f_{2r+2}^{(2n)} \sinh(2r+2)z, \quad (1 \text{ a})$$

$$F_{2n+1}(z, q) = C_{2n+1}(q) \sum_{r=0}^{\infty} f_{2r+1}^{(2n+1)} \sinh(2r+1)z; \quad (2 \text{ a})$$

$$G_{2n+1}(z, q) = S_{2n+1}(q) \sum_{r=0}^{\infty} g_{2r+1}^{(2n+1)} \cosh(2r+1)z, \quad (3 \text{ a})$$

$$G_{2n+2}(z, q) = S_{2n+2}(q) \sum_{r=0}^{\infty} g_{2r}^{(2n+2)} \cosh 2rz. \quad (4 \text{ a})$$

By § 7.22, when  $q \rightarrow 0$ ,  $\text{Fe}_m(z, q) \rightarrow +\sinh mz$ ,  $\text{Ge}_m(z, q) \rightarrow +\cosh mz$ . The complete solution of the differential equation for  $q$  positive is

$$y(z) = A \text{Ce}_m(z, q) + B \text{Fe}_m(z, q) \quad (a_m) \quad (5)$$

or 
$$y(z) = \bar{A} \text{Se}_m(z, q) + \bar{B} \text{Ge}_m(z, q) \quad (b_m), \quad (6)$$

according as the characteristic number is  $a_m$  or  $b_m$ . Either (5) or (6) constitutes a fundamental system of solutions for the modified Mathieu functions of integral order.

**7.62. Second solutions corresponding to  $\text{Ce}_m(z, -q)$ ,  $\text{Se}_m(z, -q)$ .** These are solutions of  $y'' - (a + 2q \cosh 2z)y = 0$ . They are derived from (1)–(4) § 7.61 by writing  $(\frac{1}{2}\pi i + z)$  for  $z$ , since this alters the sign of  $q$  in the equation in § 7.61. Thus from (1) § 7.61 we have

$$\begin{aligned} & (-1)^n \text{Fe}_{2n}(\tfrac{1}{2}\pi i + z, q) \\ &= C_{2n}(q) \left[ (\tfrac{1}{2}\pi i + z) \text{Ce}_{2n}(z, -q) + (-1)^n \sum_{r=0}^{\infty} (-1)^{r+1} f_{2r+2}^{(2n)} \sinh(2r+2)z \right]. \dagger \end{aligned} \quad (1)$$

Now, if  $z$  is real, the r.h.s. represents a complex function, but it is expedient that the function defined should be real. Since  $\text{Ce}_{2n}(z, -q)$  is a first solution of the differential equation, there is no need to retain  $\frac{1}{2}\pi i \text{Ce}_{2n}(z, -q)$ . Accordingly we adopt the following definitions:

$$\begin{aligned} & \text{Fe}_{2n}(z, -q) \\ &= C_{2n}(q) \left[ z \text{Ce}_{2n}(z, -q) + (-1)^n \sum_{r=0}^{\infty} (-1)^{r+1} f_{2r+2}^{(2n)} \sinh(2r+2)z \right] \quad (a_{2n}), \end{aligned} \quad (2)$$

† This result is obtained also, if we take  $-i \text{fe}_{2n}(iz, -q)$ , using (1) § 7.60.

$$\begin{aligned} \text{Fe}_{2n+1}(z, -q) \\ = -S_{2n+1}(q) \left[ z \text{Ce}_{2n+1}(z, -q) + (-1)^{n+1} \sum_{r=0}^{\infty} (-1)^r g_{2r+1}^{(2n+1)} \sinh(2r+1)z \right] \\ (b_{2n+1}); \quad (3) \end{aligned}$$

$$\begin{aligned} \text{Ge}_{2n+1}(z, -q) \\ = C_{2n+1}(q) \left[ z \text{Se}_{2n+1}(z, -q) + (-1)^n \sum_{r=0}^{\infty} (-1)^r f_{2r+1}^{(2n+1)} \cosh(2r+1)z \right] \\ (a_{2n+1}), \quad (4) \end{aligned}$$

$$\begin{aligned} \text{Ge}_{2n+2}(z, -q) \\ = -S_{2n+2}(q) \left[ z \text{Se}_{2n+2}(z, -q) + (-1)^n \sum_{r=0}^{\infty} (-1)^r g_{2r}^{(2n+2)} \cosh 2rz \right] \\ (b_{2n+2}). \quad (5) \end{aligned}$$

By § 7.22, when  $q \rightarrow 0$ ,

$$\text{Fe}_m(z, -q) \rightarrow +\sinh mz, \quad \text{Ge}_m(z, -q) \rightarrow +\cosh mz,$$

these being solutions of  $y'' - m^2 y = 0$ , the degenerate form of the modified Mathieu equation when  $q = 0$ . As in § 7.60 the multipliers  $(-1)^n$  ensure the conventional positive signs. The complete solution of  $y'' - (a + 2q \cosh 2z)y = 0$  for  $q$  positive, i.e.  $q$  negative in the standard form, is obtained by writing  $-q$  for  $q$  in (5), (6) § 7.61, the characteristic numbers being those above and in § 2.31.

## VIII

### SOLUTIONS IN SERIES OF BESSEL FUNCTIONS

**8.10. First solution of  $y'' - (a - 2q \cosh 2z)y = 0$ ,  $q > 0$ .** Let  $u = 2k \cosh z$ ,  $k^2 = q > 0$ , and the equation becomes [52]

$$(u^2 - 4k^2)y'' + uy' + (u^2 - p^2)y = 0, \quad (1)$$

with  $p^2 = (a + 2k^2)$ . Assume a solution

$$y = \sum_{r=0}^{\infty} (-1)^r c_{2r} J_{2r}(u), \quad (2)$$

and substitute it into (1); then we get

$$\sum_{r=0}^{\infty} (-1)^r c_{2r} [(u^2 - 4k^2)J_{2r}'' + uJ_{2r}' + (u^2 - p^2)J_{2r}] = 0. \quad (3)$$

From Bessel's equation

$$u^2 J_{2r}'' + uJ_{2r}' + u^2 J_{2r} = 4r^2 J_{2r}, \quad (4)$$

and by recurrence relations

$$4J_{2r}'' = J_{2r-2} - 2J_{2r} + J_{2r+2}. \quad (5)$$

Substituting (4), (5) into (3) leads to

$$\sum_{r=0}^{\infty} (-1)^r c_{2r} [(4r^2 - a)J_{2r} - k^2(J_{2r-2} + J_{2r+2})] = 0, \quad (6)$$

since  $2k^2 - p^2 = -a$ . Equating coefficients of  $J_{2r}$  to zero ( $r = 0, 1, 2, \dots$ ), we obtain

$$J_0 \quad ac_0 - k^2 c_2 = 0, \quad (7)$$

$$J_2 \quad (a - 4)c_2 - k^2(c_4 + 2c_0) = 0, \quad (8)$$

$$J_{2r} \quad (a - 4r^2)c_{2r} - k^2(c_{2r+2} + c_{2r-2}) = 0 \quad (r \geq 2). \quad (9)$$

Now (9) is a linear difference equation of the second order, and it has two independent solutions, so the complete solution takes the form

$$u_{2r} = \gamma c_{2r} + \delta d_{2r}, \quad (10)$$

where  $\gamma, \delta$  are arbitrary constants. When  $r \rightarrow +\infty$ ,  $c_{2r} \rightarrow 0$ , while by § 3.21  $|d_{2r}| \rightarrow \infty$  in such a way that  $|v_{2r+2}| \sim 4(r+1)^2 q^{-1}$ . Thus by 2° § 8.50, (2) would diverge, so the solution  $d_{2r}$  is inadmissible, i.e.  $\delta = 0$ .† Since (7)–(9) are identical in form with the recurrence relations (1) § 3.10 for the  $A$  in

$$\text{Ce}_{2n}(z, q) = \sum_{r=0}^{\infty} A_{2r}^{(2n)} \cosh 2rz \quad (a_{2n}), \quad (11)$$

† See § 3.21.

it follows that  $c_{2r}$  is a constant multiple of  $A_{2r}^{(2n)}$ . Hence

$$K \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} J_{2r}(2k \cosh z) \quad (12)$$

is a solution of  $y'' - (a - 2q \cosh 2z)y = 0$ . Now both (11), (12) are even functions of  $z$  with period  $\pi i$  and they satisfy this equation for the same  $(a, q)$ . Thus one is a constant multiple of the other. Accordingly

$$\text{Ce}_{2n}(z, q) = K \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} J_{2r}(2k \cosh z). \quad (13)$$

By 2° § 8.50 this series is absolutely and uniformly convergent in any finite part of the  $z$ -plane. Putting  $z = \frac{1}{2}\pi i$  gives

$$K = \text{ce}_{2n}(\frac{1}{2}\pi, q)/A_0^{(2n)}, \quad (14)$$

since all the B.F. vanish except when  $r = 0$ , giving  $J_0(0) = 1$ . Hence from (13), (14) it follows that

$$\text{Ce}_{2n}(z, q) = \frac{\text{ce}_{2n}(\frac{1}{2}\pi, q)}{A_0^{(2n)}} \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} J_{2r}(2k \cosh z) \quad (a_{2n}). \quad (15)$$

By taking  $u = 2k \sinh z$  in the differential equation and proceeding as shown above, we derive the solution

$$K_1 \sum_{r=0}^{\infty} A_{2r}^{(2n)} J_{2r}(2k \sinh z). \quad (16)$$

This is even with period  $\pi i$ , and is also a constant multiple of  $\text{Ce}_{2n}(z, q)$ . With  $z = 0$ ,  $K_1 = \text{ce}_{2n}(0, q)/A_0^{(2n)}$ , so

$$\text{Ce}_{2n}(z, q) = \frac{\text{ce}_{2n}(0, q)}{A_0^{(2n)}} \sum_{r=0}^{\infty} A_{2r}^{(2n)} J_{2r}(2k \sinh z) \quad (a_{2n}). \quad (17)$$

Thus (15), (17) are alternative forms of the first solution.

The multipliers  $K$  pertaining to various functions in the sections which follow are derived in Chapter X.

**8.11. The second solution.** Since the recurrence relations for the Bessel functions  $Y_{2r}$  are identical in form with those for  $J_{2r}$ , and both functions satisfy the same differential equation, it follows from (15), (17) § 8.10 that the function defined by

$$\begin{aligned} \text{Fey}_{2n}(z, q) &= \frac{\text{ce}_{2n}(\frac{1}{2}\pi, q)}{A_0^{(2n)}} \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} Y_{2r}(2k \cosh z) \quad (|\cosh z| > 1) \\ &= \frac{\text{ce}_{2n}(0, q)}{A_0^{(2n)}} \sum_{r=0}^{\infty} A_{2r}^{(2n)} Y_{2r}(2k \sinh z) \quad \left( \begin{array}{l} |\sinh z| > 1 \\ R(z) > 0 \end{array} \right) \end{aligned} \quad (1) \dagger \quad (2)$$

† The  $y$  in  $\text{Fey}$  signifies the  $Y$ -Bessel function.

is an independent solution for  $a = a_{2n}$ . The restrictions indicated on the right are necessary for absolute and uniform convergence, and are obtained in 3° § 8.50. Actually, although both series are non-uniformly convergent as  $|\cosh z|$  or  $|\sinh z| \rightarrow 1$ , they converge when these arguments are unity, but the rate of convergence is dead slow! Solutions in B.F. products are free from these disadvantages (see § 13.61).

Using the well-known expansion for the  $Y$  functions in (1), (2), we find that

$$\text{Fey}_{2n}(z, q) = \frac{2}{\pi} \left[ \gamma + \log \left( k \frac{\cosh z}{\sinh z} \right) \right] \text{Ce}_{2n}(z, q) + \text{two double summations.} \quad (3)$$

$\gamma$  being Euler's constant. The first member on the r.h.s. may be written

$$\frac{2}{\pi} [\gamma + \log k + \log \frac{1}{2} (1 \pm e^{-2z}) + z] \text{Ce}_{2n}(z, q), \quad (4)$$

from which it is clear that neither (1) nor (2) is periodic in  $z$ . In Chapter XIII we shall obtain a relationship between  $\text{Fey}_{2n}(z, q)$  and the alternative second solution  $\text{Fe}_{2n}(z, q)$  of Chapter VII. It is not possible to do this using the series (1), (2), since the non-uniform convergence of (1) and the divergence of (2) at the origin renders term-by-term differentiation invalid.† This applies to kindred functions in succeeding sections.

The complete solution of the equation, corresponding to  $a = a_{2n}$ , is

$$y = A \text{Ce}_{2n}(z, q) + B \text{Fey}_{2n}(z, q), \quad (5)$$

where  $A, B$  are arbitrary constants. This constitutes a fundamental system.

**8.12. The solutions  $\text{Ce}_{2n+1}(z, q)$ ,  $\text{Fey}_{2n+1}(z, q)$ .** By analysis similar to that in § 8.10, we obtain (1), (3) below:

$$\begin{aligned} \text{Ce}_{2n+1}(z, q) &= - \frac{\text{ce}'_{2n+1}(\frac{1}{2}\pi, q)}{k A_1^{(2n+1)}} \sum_{r=0}^{\infty} (-1)^r A_{2r+1}^{(2n+1)} J_{2r+1}(2k \cosh z) \quad (a_{2n+1}) \quad (1) \\ &= \frac{\text{ce}_{2n+1}(0, q)}{k A_1^{(2n+1)}} \coth z \sum_{r=0}^{\infty} (2r+1) A_{2r+1}^{(2n+1)} J_{2r+1}(2k \sinh z); \quad (2) \end{aligned}$$

† The result of so doing to (1) gives  $\text{Fey}_{2n}(0, q) = 0$ , which is untrue by virtue of (9) § 13.31.

$\text{Fey}_{2n+1}(z, q)$

$$= -\frac{\text{ce}'_{2n+1}(\frac{1}{2}\pi, q)}{kA_1^{(2n+1)}} \sum_{r=0}^{\infty} (-1)^r A_{2r+1}^{(2n+1)} Y_{2r+1}(2k \cosh z) \quad (3)$$

$$= \frac{\text{ce}_{2n+1}(0, q)}{kA_1^{(2n+1)}} \coth z \sum_{r=0}^{\infty} (2r+1) A_{2r+1}^{(2n+1)} Y_{2r+1}(2k \sinh z). \quad (4)$$

The restrictions at (1), (2) § 8.11 apply to (3), (4) respectively.

To derive (2), (4), we observe that  $\text{Ce}_{2n+1}(z, q)$  is an even function of  $z$ , whereas  $J_{2r+1}(2k \sinh z)$  is an odd one. If we multiply the latter by the odd function  $\coth z$  the product function is even. Assuming that  $y = \coth z w(u)$ , with  $u = 2k \sinh z$ , and proceeding as in § 8.10 leads to the series solutions (2), (4). By virtue of the logarithmic term in the expansion of  $Y_{2r+1}$ , these solutions are non-periodic, but (1), (2) have period  $2\pi i$ . The complete solution takes the same form as (5) § 8.11.

**8.13. The solutions  $\text{Se}_m(z, q)$ ,  $\text{Gey}_m(z, q)$ .** As before we assume a Bessel series with argument  $u = 2k \cosh z$ , namely,

$$w(u) = \sum_{r=0}^{\infty} (-1)^r c_{2r+1} J_{2r+1}(u), \quad (1)$$

this being an even function of  $z$ . But  $\text{Se}_{2n+1}(z, q)$  is odd in  $z$ , so we take the odd function

$$y = \tanh z w(u) \quad (2)$$

and substitute it in the differential equation. Then the transformed equation is [52]

$$(u^2 - 4k^2)w'' + uw' + (u^2 - p^2)w + 8k^2 \frac{d}{du}(w/u) = 0. \quad (3)$$

Proceeding as in § 8.10, we find that

$$c_{2r+1} = K_1(2r+1)B_{2r+1}^{(2n+1)}, \quad (4)$$

$K_1$  being a constant multiplier. Hence

$$\tanh z w(u) = \tanh z \sum_{r=0}^{\infty} (-1)^r (2r+1) B_{2r+1}^{(2n+1)} J_{2r+1}(2k \cosh z) \quad (5)$$

is a first solution of  $y'' - (a - 2q \cosh 2z)y$  corresponding to the characteristic number  $a = b_{2n+1}$ . By analysis of the type in § 8.10 we obtain

$\text{Se}_{2n+1}(z, q)$

$$= \frac{\text{se}_{2n+1}(\frac{1}{2}\pi, q)}{kB_1^{(2n+1)}} \tanh z \sum_{r=0}^{\infty} (-1)^r (2r+1) B_{2r+1}^{(2n+1)} J_{2r+1}(2k \cosh z) \quad (b_{2n+1}) \quad (6)$$

$$= \frac{\text{se}'_{2n+1}(0, q)}{kB_1^{(2n+1)}} \sum_{r=0}^{\infty} B_{2r+1}^{(2n+1)} J_{2r+1}(2k \sinh z). \quad (7)$$

These representations both have period  $2\pi i$ . Since  $\sinh z$  is odd in  $z$ , (7) was obtained by substituting (1) with  $u = 2k \sinh z$  in the differential equation.

The remaining solutions derived as shown above and in previous sections are

$\text{Gey}_{2n+1}(z, q)$

$$= \frac{\text{se}_{2n+1}(\frac{1}{2}\pi, q)}{k B_1^{(2n+1)}} \tanh z \sum_{r=0}^{\infty} (-1)^r (2r+1) B_{2r+1}^{(2n+1)} Y_{2r+1}(2k \cosh z) \quad (b_{2n+1}) \quad (8)$$

$$= \frac{\text{se}'_{2n+1}(0, q)}{k B_1^{(2n+1)}} \sum_{r=0}^{\infty} B_{2r+1}^{(2n+1)} Y_{2r+1}(2k \sinh z). \quad (9)$$

These are the second solutions corresponding to (6), (7). By virtue of the logarithmic term in the expansion of the  $Y$  function, (8), (9) are non-periodic. Attention is drawn to the restrictions and comments in § 8.11.

$\text{Se}_{2n+2}(z, q)$

$$= -\frac{\text{se}'_{2n+2}(\frac{1}{2}\pi, q)}{k^2 B_2^{(2n+2)}} \tanh z \sum_{r=0}^{\infty} (-1)^r (2r+2) B_{2r+2}^{(2n+2)} J_{2r+2}(2k \cosh z) \quad (b_{2n+2}) \quad (10)$$

$$= \frac{\text{se}'_{2n+2}(0, q)}{k^2 B_2^{(2n+2)}} \coth z \sum_{r=0}^{\infty} (2r+2) B_{2r+2}^{(2n+2)} J_{2r+2}(2k \sinh z). \quad (11)$$

The B.F. in (10), (11) being of even order are both even in  $z$ , but the hyperbolic multipliers are both odd. Hence the representations are odd in  $z$ , also they have period  $\pi i$ .

The second solutions (apart from  $\text{Ge}_m(z, q)$  in Chapter VII) corresponding to (10), (11) are

$\text{Gey}_{2n+2}(z, q)$

$$= -\frac{\text{se}'_{2n+2}(\frac{1}{2}\pi, q)}{k^2 B_2^{(2n+2)}} \tanh z \sum_{r=0}^{\infty} (-1)^r (2r+2) B_{2r+2}^{(2n+2)} Y_{2r+2}(2k \cosh z) \quad (b_{2n+2}) \quad (12)$$

$$= \frac{\text{se}'_{2n+2}(0, q)}{k^2 B_2^{(2n+2)}} \coth z \sum_{r=0}^{\infty} (2r+2) B_{2r+2}^{(2n+2)} Y_{2r+2}(2k \sinh z). \quad (13)$$

See remarks below (9) above. The complete solution takes the form

$$y = A \text{Se}_m(z, q) + B \text{Gey}_m(z, q). \quad (14)$$

**8.14. The solutions**  $\text{Fek}_m(z, q)$ ,  $\text{Gek}_m(z, q)$ . These are derived from §§ 8.11–8.13 by expressing the  $Y$  functions in the series for

$\text{Fey}_m(z, q)$ ,  $\text{Gey}_m(z, q)$  in terms of the  $J$ - and  $K$ -Bessel functions. Thus

$$K_\nu(u) = \frac{1}{2}\pi e^{i\pi(\nu+1)i} H_\nu^{(1)}(iu), \quad (1)$$

$$\text{so} \quad Y_\nu(u) = iJ_\nu(u) - \frac{2}{\pi} e^{-i\pi\nu i} K_\nu(-iu). \quad (2)$$

Writing  $\nu = 2r$ , and applying (2) to (1) § 8.11 yields

$$\begin{aligned} \text{Fey}_{2n}(z, q) &= \frac{\text{ce}_{2n}(\frac{1}{2}\pi, q)}{A_0^{(2n)}} \times \\ &\times \left[ i \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} J_{2r}(2k \cosh z) - \frac{2}{\pi} \sum_{r=0}^{\infty} A_{2r}^{(2n)} K_{2r}(-2ik \cosh z) \right] \\ &\quad (k > 0, |\cosh z| > 1) \quad (a_{2n}) \quad (3) \end{aligned}$$

$$= i \text{Ce}_{2n}(z, q) - 2 \text{Fek}_{2n}(z, q), \quad (4)$$

where we adopt the definition

$$\text{Fek}_{2n}(z, q) = \frac{\text{ce}_{2n}(\frac{1}{2}\pi, q)}{\pi A_0^{(2n)}} \sum_{r=0}^{\infty} A_{2r}^{(2n)} K_{2r}(-2ik \cosh z) \quad (a_{2n}). \quad (5)$$

In like manner (2) § 8.11 yields

$$\text{Fek}_{2n}(z, q) = \frac{\text{ce}_{2n}(0, q)}{\pi A_0^{(2n)}} \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} K_{2r}(-2ik \sinh z). \quad (6)$$

Since  $\text{Fey}_{2n}(z, q)$ ,  $\text{Ce}_{2n}(z, q)$  are real if  $z$  is real, it follows from (4) that  $\text{Fek}_{2n}(z, q)$  is complex. The restrictions at (1), (2) § 8.11 apply here, and convergence is considered in § 8.50. By virtue of the logarithmic term in the series for the  $K$  function, (5), (6) are non-periodic in  $z$ . These remarks apply also to the remaining functions given below:

$$\text{Fey}_{2n+1}(z, q) = i[\text{Ce}_{2n+1}(z, q) + 2 \text{Fek}_{2n+1}(z, q)], \quad (7)$$

with

$$\begin{aligned} \text{Fek}_{2n+1}(z, q) &= -\frac{\text{ce}'_{2n+1}(\frac{1}{2}\pi, q)}{\pi k A_1^{(2n+1)}} \sum_{r=0}^{\infty} A_{2r+1}^{(2n+1)} K_{2r+1}(-2ik \cosh z) \quad (a_{2n+1}) \quad (8) \end{aligned}$$

$$= \frac{\text{ce}_{2n+1}(0, q)}{\pi k A_1^{(2n+1)}} \coth z \sum_{r=0}^{\infty} (-1)^r (2r+1) A_{2r+1}^{(2n+1)} K_{2r+1}(-2ik \sinh z). \quad (9)$$

$$\text{Gey}_{2n+1}(z, q) = i[\text{Se}_{2n+1}(z, q) + 2 \text{Gek}_{2n+1}(z, q)], \quad (10)$$

with

$$\begin{aligned} \text{Gek}_{2n+1}(z, q) &= \frac{\text{se}_{2n+1}(\frac{1}{2}\pi, q)}{\pi k B_1^{(2n+1)}} \tanh z \sum_{r=0}^{\infty} (2r+1) B_{2r+1}^{(2n+1)} K_{2r+1}(-2ik \cosh z) \quad (b_{2n+1}) \\ &= \frac{\text{se}'_{2n+1}(0, q)}{\pi k B_1^{(2n+1)}} \sum_{r=0}^{\infty} (-1)^r B_{2r+1}^{(2n+1)} K_{2r+1}(-2ik \sinh z). \end{aligned} \quad (11)$$

$$= \frac{\text{se}'_{2n+1}(0, q)}{\pi k B_1^{(2n+1)}} \sum_{r=0}^{\infty} (-1)^r B_{2r+1}^{(2n+1)} K_{2r+1}(-2ik \sinh z). \quad (12)$$

$$\text{Gey}_{2n+2}(z, q) = i \text{Se}_{2n+2}(z, q) - 2 \text{Gek}_{2n+2}(z, q), \quad (13)$$

with

$$\begin{aligned} \text{Gek}_{2n+2}(z, q) &= \frac{\text{se}_{2n+2}(\frac{1}{2}\pi, q)}{\pi k^2 B_2^{(2n+2)}} \tanh z \sum_{r=0}^{\infty} (2r+2) B_{2r+2}^{(2n+2)} K_{2r+2}(-2ik \cosh z) \quad (b_{2n+2}) \\ &= -\frac{\text{se}'_{2n+2}(0, q)}{\pi k^2 B_2^{(2n+2)}} \coth z \sum_{r=0}^{\infty} (-1)^r (2r+2) B_{2r+2}^{(2n+2)} K_{2r+2}(-2ik \sinh z). \end{aligned} \quad (14)$$

$$= -\frac{\text{se}'_{2n+2}(0, q)}{\pi k^2 B_2^{(2n+2)}} \coth z \sum_{r=0}^{\infty} (-1)^r (2r+2) B_{2r+2}^{(2n+2)} K_{2r+2}(-2ik \sinh z). \quad (15)$$

If desired the  $K$  functions may be expressed in terms of Hankel functions by aid of (1).

The complete solutions given at (5) § 8.11, (14) § 8.13 may sometimes be unsuitable. However, in any complete solution of that type it is permissible to substitute  $\text{Fek}_m$  for  $\text{Fey}_m$ , and  $\text{Gek}_m$  for  $\text{Gey}_m$ , by virtue of (4), (7), (10), (13).

**8.20. First solution of  $y'' + (a - 2q \cos 2z)y = 0$ .** By writing  $-iz$  for  $z$  in the series for  $\text{Ce}_m$ ,  $\text{Se}_m$  in §§ 8.10, 8.12, 8.13 we obtain

$$\text{ce}_{2n}(z, q) = \frac{\text{ce}_{2n}(\frac{1}{2}\pi, q)}{A_0^{(2n)}} \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} J_{2r}(2k \cos z) \quad (a_{2n}) \quad (1)$$

$$= \frac{\text{ce}_{2n}(0, q)}{A_0^{(2n)}} \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} J_{2r}(2k \sin z), \quad (2)$$

$$\text{ce}_{2n+1}(z, q) = -\frac{\text{ce}'_{2n+1}(\frac{1}{2}\pi, q)}{k A_1^{(2n+1)}} \sum_{r=0}^{\infty} (-1)^r A_{2r+1}^{(2n+1)} J_{2r+1}(2k \cos z) \quad (a_{2n+1}) \quad (3)$$

$$= \frac{\text{ce}_{2n+1}(0, q)}{k A_1^{(2n+1)}} \cot z \sum_{r=0}^{\infty} (-1)^r (2r+1) A_{2r+1}^{(2n+1)} J_{2r+1}(2k \sin z), \quad (4)$$

$$\begin{aligned} \text{se}_{2n+1}(z, q) &= \frac{\text{se}_{2n+1}(\frac{1}{2}\pi, q)}{k B_1^{(2n+1)}} \tan z \sum_{r=0}^{\infty} (-1)^r (2r+1) B_{2r+1}^{(2n+1)} J_{2r+1}(2k \cos z) \\ &\quad (b_{2n+1}) \end{aligned} \quad (5)$$

$$= \frac{\text{se}'_{2n+1}(0, q)}{k B_1^{(2n+1)}} \sum_{r=0}^{\infty} (-1)^r B_{2r+1}^{(2n+1)} J_{2r+1}(2k \sin z), \quad (6)$$

$$\text{se}_{2n+2}(z, q) = -\frac{\text{se}'_{2n+2}(\frac{1}{2}\pi, q)}{k^2 B_{2n+2}^{(2n+2)}} \tan z \sum_{r=0}^{\infty} (-1)^r (2r+2) B_{2r+2}^{(2n+2)} J_{2r+2}(2k \cos z) \quad (b_{2n+2}) \quad (7)$$

$$= \frac{\text{se}'_{2n+2}(0, q)}{k^2 B_{2n+2}^{(2n+2)}} \cot z \sum_{r=0}^{\infty} (-1)^r (2r+2) B_{2r+2}^{(2n+2)} I_{2r+2}(2k \sin z). \quad (8)$$

**8.30. Solutions of  $y'' - (a + 2q \cosh 2z)y = 0$ ,  $q > 0$ .** If we write  $(\frac{1}{2}\pi i + z)$  for  $z$  in  $y'' - (a - 2q \cosh 2z)y = 0$ , it takes the above form, i.e. the sign of  $q$  is changed. Making this change of variable in series derived in § 8.10 et seq. leads to the following representations:†

$$\text{Ce}_{2n}(z, -q) = (-1)^n \text{Ce}_{2n}(\frac{1}{2}\pi i + z, q) \quad (a_{2n}) \quad (1)$$

$$= (-1)^n \frac{\text{ce}_{2n}(\frac{1}{2}\pi, q)}{A_0^{(2n)}} \sum_{r=0}^{\infty} A_{2r}^{(2n)} I_{2r}(2k \sinh z) \quad (2)$$

$$= (-1)^n \frac{\text{ce}_{2n}(0, q)}{A_0^{(2n)}} \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} I_{2r}(2k \cosh z). \quad (3)$$

The multiplier  $(-1)^n$  is needed by virtue of that in § 2.31.

$$\text{Fey}_{2n}(z, -q) = (-1)^n \text{Fey}_{2n}(\frac{1}{2}\pi i + z, q) \quad (a_{2n}) \quad (4)$$

$$= (-1)^n \frac{\text{ce}_{2n}(\frac{1}{2}\pi, q)}{A_0^{2n}} \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} Y_{2r}(2ik \sinh z) \quad (5)$$

$$= (-1)^n \frac{\text{ce}_{2n}(0, q)}{A_0^{(2n)}} \sum_{r=0}^{\infty} A_{2r}^{(2n)} Y_{2r}(2ik \cosh z). \quad (6)$$

$$\text{Fek}_{2n}(z, -q) = (-1)^n \text{Fek}_{2n}(\frac{1}{2}\pi i + z, q) \quad (7)$$

$$= (-1)^n \frac{\text{ce}_{2n}(\frac{1}{2}\pi, q)}{\pi A_0^{(2n)}} \sum_{r=0}^{\infty} A_{2r}^{(2n)} K_{2r}(2k \sinh z) \quad (8)$$

$$= (-1)^n \frac{\text{ce}_{2n}(0, q)}{\pi A_0^{(2n)}} \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} K_{2r}(2k \cosh z). \quad (9)$$

$$\text{Fey}_{2n}(z, -q) = i \text{Ce}_{2n}(z, -q) - 2 \text{Fek}_{2n}(z, -q). \quad (10)$$

$$\text{Ce}_{2n+1}(z, -q) = (-1)^{n+1} i \text{Se}_{2n+1}(\frac{1}{2}\pi i + z, q) \quad (b_{2n+1}) \quad (11)$$

$$= (-1)^n \frac{\text{se}_{2n+1}(\frac{1}{2}\pi, q)}{k B_1^{(2n+1)}} \coth z \sum_{r=0}^{\infty} (2r+1) B_{2r+1}^{(2n+1)} I_{2r+1}(2k \sinh z) \quad (12)$$

$$= (-1)^n \frac{\text{se}'_{2n+1}(0, q)}{k B_1^{(2n+1)}} \sum_{r=0}^{\infty} (-1)^r B_{2r+1}^{(2n+1)} I_{2r+1}(2k \cosh z). \quad (13)$$

† Formulae 2, 3, 9, 12, 13, 19, 22, 23, 29, 32, 33, 39 are given in reference [6] without the multipliers external to the  $\Sigma$ . The method of derivation differs from that used here.

$$\begin{aligned} \text{Fey}_{2n+1}(z, -q) \\ = (-1)^{n+1} i \text{Gey}_{2n+1}(\tfrac{1}{2}\pi i + z, q) \quad (b_{2n+1}) \end{aligned} \quad (14)$$

$$= (-1)^{n+1} i \frac{\text{se}_{2n+1}(\tfrac{1}{2}\pi, q)}{k B_1^{(2n+1)}} \coth z \sum_{r=0}^{\infty} (-1)^r (2r+1) B_{2r+1}^{(2n+1)} Y_{2r+1}(2ik \sinh z) \quad (15)$$

$$= (-1)^{n+1} i \frac{\text{se}'_{2n+1}(0, q)}{k B_1^{(2n+1)}} \sum_{r=0}^{\infty} B_{2r+1}^{(2n+1)} Y_{2r+1}(2ik \cosh z). \quad (16)$$

$$\begin{aligned} \text{Fek}_{2n+1}(z, -q) \\ = (-1)^n \text{Gek}_{2n+1}(\tfrac{1}{2}\pi i + z, q) \end{aligned} \quad (17)$$

$$= (-1)^n \frac{\text{se}_{2n+1}(\tfrac{1}{2}\pi, q)}{\pi k B_1^{(2n+1)}} \coth z \sum_{r=0}^{\infty} (2r+1) B_{2r+1}^{(2n+1)} K_{2r+1}(2k \sinh z) \quad (18)$$

$$= (-1)^n \frac{\text{se}'_{2n+1}(0, q)}{\pi k B_1^{(2n+1)}} \sum_{r=0}^{\infty} (-1)^r B_{2r+1}^{(2n+1)} K_{2r+1}(2k \cosh z). \quad (19)$$

$$\text{Fey}_{2n+1}(z, -q) = i \text{Ce}_{2n+1}(z, -q) + 2 \text{Fek}_{2n+1}(z, -q). \quad (20)$$

$$\begin{aligned} \text{Se}_{2n+1}(z, -q) \\ = (-1)^{n+1} i \text{Ce}_{2n+1}(\tfrac{1}{2}\pi i + z, q) \quad (a_{2n+1}) \end{aligned} \quad (21)$$

$$= (-1)^{n+1} i \frac{\text{ce}'_{2n+1}(\tfrac{1}{2}\pi, q)}{k A_1^{(2n+1)}} \sum_{r=0}^{\infty} A_{2r+1}^{(2n+1)} I_{2r+1}(2k \sinh z) \quad (22)$$

$$= (-1)^n \frac{\text{ce}_{2n+1}(0, q)}{k A_1^{(2n+1)}} \tanh z \sum_{r=0}^{\infty} (-1)^r (2r+1) A_{2r+1}^{(2n+1)} I_{2r+1}(2k \cosh z). \quad (23)$$

$$\begin{aligned} \text{Gey}_{2n+1}(z, -q) \\ = (-1)^{n+1} i \text{Fey}_{2n+1}(\tfrac{1}{2}\pi i + z, q) \quad (a_{2n+1}) \end{aligned} \quad (24)$$

$$= (-1)^{n+1} i \frac{\text{ce}'_{2n+1}(\tfrac{1}{2}\pi, q)}{i A_1^{(2n+1)}} \sum_{r=0}^{\infty} (-1)^r A_{2r+1}^{(2n+1)} Y_{2r+1}(2ik \sinh z) \quad (25)$$

$$= (-1)^{n+1} i \frac{\text{ce}_{2n+1}(0, q)}{k A_1^{(2n+1)}} \tanh z \sum_{r=0}^{\infty} (2r+1) A_{2r+1}^{(2n+1)} Y_{2r+1}(2ik \cosh z). \quad (26)$$

$$\begin{aligned} \text{Gek}_{2n+1}(z, -q) \\ = (-1)^n \text{Fek}_{2n+1}(\tfrac{1}{2}\pi i + z, q) \end{aligned} \quad (27)$$

$$= (-1)^{n+1} \frac{\text{ce}'_{2n+1}(\tfrac{1}{2}\pi, q)}{\pi k A_1^{(2n+1)}} \sum_{r=0}^{\infty} A_{2r+1}^{(2n+1)} K_{2r+1}(2k \sinh z) \quad (28)$$

$$= (-1)^n \frac{\text{ce}_{2n+1}(0, q)}{\pi k A_1^{(2n+1)}} \tanh z \sum_{r=0}^{\infty} (-1)^r (2r+1) A_{2r+1}^{(2n+1)} K_{2r+1}(2k \cosh z). \quad (29)$$

$$\text{Gey}_{2n+1}(z, -q) = i \text{Se}_{2n+1}(z, -q) + 2 \text{Gek}_{2n+1}(z, -q). \quad (30)$$

$$\text{Se}_{2n+2}(z, -q) = (-1)^{n+1} \text{Se}_{2n+2}(\tfrac{1}{2}\pi i + z, q) \quad (b_{2n+2}) \quad (31)$$

$$= (-1)^{n+1} \frac{\text{se}'_{2n+2}(\tfrac{1}{2}\pi, q)}{k^2 B_2^{(2n+2)}} \coth z \sum_{r=0}^{\infty} (2r+2) B_{2r+2}^{(2n+2)} I_{2r+2}(2k \sinh z) \quad (32)$$

$$= (-1)^n \frac{\text{se}'_{2n+2}(0, q)}{k^2 B_2^{(2n+2)}} \tanh z \sum_{r=0}^{\infty} (-1)^r (2r+2) B_{2r+2}^{(2n+2)} I_{2r+2}(2k \cosh z). \quad (33)$$

$$\text{Gey}_{2n+2}(z, -q) = (-1)^{n+1} \text{Gey}_{2n+2}(\tfrac{1}{2}\pi i + z, q) \quad (b_{2n+2}) \quad (34)$$

$$= (-1)^n \frac{\text{se}'_{2n+2}(\tfrac{1}{2}\pi, q)}{k^2 B_2^{(2n+2)}} \coth z \sum_{r=0}^{\infty} (-1)^r (2r+2) B_{2r+2}^{(2n+2)} Y_{2r+2}(2ik \sinh z) \quad (35)$$

$$= (-1)^{n+1} \frac{\text{se}'_{2n+2}(0, q)}{k^2 B_2^{(2n+2)}} \tanh z \sum_{r=0}^{\infty} (2r+2) B_{2r+2}^{(2n+2)} Y_{2r+2}(2ik \cosh z). \quad (36)$$

$$\text{Gek}_{2n+2}(z, -q) = (-1)^{n+1} \text{Gek}_{2n+2}(\tfrac{1}{2}\pi i + z, q) \quad (37)$$

$$= (-1)^{n+1} \frac{\text{se}'_{2n+2}(\tfrac{1}{2}\pi, q)}{\pi k^2 B_2^{(2n+2)}} \coth z \sum_{r=0}^{\infty} (2r+2) B_{2r+2}^{(2n+2)} K_{2r+2}(2k \sinh z) \quad (38)$$

$$= (-1)^n \frac{\text{se}'_{2n+2}(0, q)}{\pi k^2 B_2^{(2n+2)}} \tanh z \sum_{r=0}^{\infty} (-1)^r (2r+2) B_{2r+2}^{(2n+2)} K_{2r+2}(2k \cosh z). \quad (39)$$

$$\text{Gey}_{2n+2}(z, -q) = i \text{Se}_{2n+2}(z, -q) - 2 \text{Gek}_{2n+2}(z, -q). \quad (40)$$

The functions involving the  $Y$ -Bessel function are complex, but those involving the  $K$ -Bessel function are real, if  $z$  is real.

**8.40. First solution of  $y'' + (a + 2q \cos 2z)y = 0, q > 0$ .** This may be derived by writing  $-iz$  for  $z$  in the first solution of

$$y'' - (a + 2q \cosh 2z)y = 0$$

given in § 8.30, or by putting  $(\tfrac{1}{2}\pi - z)$  for  $z$  in the first solution of  $y'' + (a - 2q \cos 2z)y = 0$  given in § 8.20. Thus we find that

$$\text{ce}_{2n}(z, -q) = (-1)^n \text{ce}_{2n}(\tfrac{1}{2}\pi - z, q) = (-1)^n \text{Ce}_{2n}(-iz, q) \quad (a_{2n}) \quad (1)$$

$$= (-1)^n \frac{\text{ce}_{2n}(\tfrac{1}{2}\pi, q)}{A_0^{(2n)}} \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} J_{2r}(2k \sin z) \quad (2)$$

$$= (-1)^n \frac{\text{ce}_{2n}(0, q)}{A_0^{(2n)}} \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} I_{2r}(2k \cos z). \quad (3)$$

$$\begin{aligned} \text{ce}_{2n+1}(z, -q) \\ = (-1)^n \text{se}_{2n+1}(\tfrac{1}{2}\pi - z, q) \quad (b_{2n+1}) \end{aligned} \quad (4)$$

$$= (-1)^n \frac{\text{se}_{2n+1}(\tfrac{1}{2}\pi, q)}{k B_1^{(2n+1)}} \cot z \sum_{r=0}^{\infty} (-1)^r (2r+1) B_{2r+1}^{(2n+1)} J_{2r+1}(2k \sin z) \quad (5)$$

$$= (-1)^n \frac{\text{se}_{2n+1}'(0, q)}{k B_1^{(2n+1)}} \sum_{r=0}^{\infty} (-1)^r B_{2r+1}^{(2n+1)} I_{2r+1}(2k \cos z). \quad (6)$$

$$\begin{aligned} \text{se}_{2n+1}(z, -q) \\ = (-1)^n \text{ce}_{2n+1}(\tfrac{1}{2}\pi - z, q) \quad (a_{2n+1}) \end{aligned} \quad (7)$$

$$= (-1)^{n+1} \frac{\text{ce}_{2n+1}'(\tfrac{1}{2}\pi, q)}{k A_1^{(2n+1)}} \sum_{r=0}^{\infty} (-1)^r A_{2r+1}^{(2n+1)} J_{2r+1}(2k \sin z) \quad (8)$$

$$= (-1)^n \frac{\text{ce}_{2n+1}(0, q)}{k A_1^{(2n+1)}} \tan z \sum_{r=0}^{\infty} (-1)^r (2r+1) A_{2r+1}^{(2n+1)} I_{2r+1}(2k \cos z). \quad (9)$$

$$\begin{aligned} \text{se}_{2n+2}(z, -q) \\ = (-1)^n \text{se}_{2n+2}(\tfrac{1}{2}\pi - z, q) \quad (b_{2n+2}) \end{aligned} \quad (10)$$

$$= (-1)^{n+1} \frac{\text{se}_{2n+2}'(\tfrac{1}{2}\pi, q)}{k^2 B_2^{(2n+2)}} \cot z \sum_{r=0}^{\infty} (-1)^r (2r+2) B_{2r+2}^{(2n+2)} J_{2r+2}(2k \sin z) \quad (11)$$

$$= (-1)^n \frac{\text{se}_{2n+2}'(0, q)}{k^2 B_2^{(2n+2)}} \tan z \sum_{r=0}^{\infty} (-1)^r (2r+2) B_{2r+2}^{(2n+2)} I_{2r+2}(2k \cos z). \quad (12)$$

### 8.50. Convergence of solutions.

1°. *Formulae asymptotic in  $m$ .* To discuss convergence we require formulae for the various Bessel functions, valid when  $m$ , the order of the function, is very large and positive, and far exceeds the argument  $|u|$ . Then the first terms in the ordinary expansions of  $J_m(u)$ ,  $I_m(u)$  predominate, and we may write

$$J_m(u) \sim I_m(u) \sim \frac{1}{m!} \left(\frac{u}{2}\right)^m. \quad (1)$$

Similarly we have

$$Y_m(u) \sim -\frac{2}{\pi} K_m(u) \sim -\frac{1}{\pi} (m-1)! \left(\frac{2}{u}\right)^m. \quad (2)$$

From (1), (2) we infer that under the above condition

$$|Y_m(u)| \gg |J_m(u)| \quad \text{and} \quad |K_m(u)| \gg |I_m(u)|. \quad (3)$$

2°. *Series involving  $J$  and  $I$  functions.* If  $2r \gg |2k \cosh z|$ , (1) 1° gives, with  $r$  extremely large,

$$J_{2r}(2k \cosh z) \sim \frac{1}{(2r)!} (k \cosh z)^{2r}. \quad (1)$$

When  $r$  is large enough, by (4) § 3.21

$$|A_{2r+2}^{(2n)}/A_{2r}^{(2n)}| \simeq |k^2|/4(r+1)^2. \quad (2)$$

Thus, taking the ratio of the moduli of the  $(r+1)$ th and  $r$ th terms in (15) § 8.10, we get

$$\left| \frac{A_{2r+2} J_{2r+2}(2k \cosh z)}{A_{2r} J_{2r}(2k \cosh z)} \right| \rightarrow \frac{|k^4| |\cosh z|^2}{16(r+1)^4} \rightarrow 0 \quad \text{as } r \rightarrow +\infty, \quad (3)$$

if  $z$  is finite but unrestricted. Hence the series is absolutely convergent. By applying the ' $M$ ' test, it may be proved to converge uniformly in any closed region of the  $z$ -plane, or in any closed interval,  $z$  real. These conclusions are applicable to all series in this chapter which involve the  $J$  and  $I$  functions.

3°. *Series involving  $Y$  and  $K$  functions.* We consider (1) § 8.11. Then (2) 1° gives

$$Y_{2r}(2k \cosh z) \sim -(2r-1)!/\pi(k \cosh z)^{2r} \quad (1)$$

and, therefore, by aid of (2) 2°,

$$\left| \frac{A_{2r+2} Y_{2r+2}(2k \cosh z)}{A_{2r} Y_{2r}(2k \cosh z)} \right| \simeq \frac{|k^2|(2r+1)2r}{4(r+1)^2 |k^2| |\cosh z|^2} \rightarrow 1/|\cosh z|^2 \quad (2)$$

as  $r \rightarrow +\infty$ . If  $|\cosh z| > 1$ , the series is absolutely convergent, and the ' $M$ ' test shows that it is uniformly convergent. As  $z \rightarrow 0$  the convergence becomes non-uniform. The series converges at the origin, but the rate of convergence is very slow. If  $|\cosh z| < 1$ ,  $z$  is imaginary,  $|\cos z| < 1$ , and the series diverges.

When the argument of the  $Y$  function is  $2k \sinh z$ , the third member of (2) is  $1/|\sinh z|^2$ . Hence the series is absolutely and uniformly convergent for  $|\sinh z| > 1$ ; for  $|\sinh z| = 1$  it converges non-uniformly, but when  $|\sinh z| < 1$  it diverges. Thus (1) § 8.11 represents  $\text{Fey}_{2n}(z, q)$  up to and including the origin, whereas (2) § 8.11 holds up to  $|\sinh z| = 1$  only, so  $z = \log_e(1+2^{\frac{1}{2}})$ . Owing to the logarithmic term in the expansions of the  $Y$  and  $K$  functions of integral order, the additional restriction that  $R(z) > 0$  must be imposed when the argument is  $2k \sinh z$ . Despite non-uniformity of convergence, as shown in § 13.60, the function  $\text{Fey}_{2n}(z, q)$  is continuous, but its derivative at  $z = 0$  cannot be obtained from either (1), (2) § 8.11 by term-by-term differentiation. These conclusions apply to all series in this chapter involving  $Y$  or  $K$  functions.

## IX

### WAVE EQUATION IN ELLIPTICAL COORDINATES: ORTHOGONALITY THEOREM

**9.10. The two-dimensional wave equation.** In two-dimensional problems associated with sinusoidal motion, the displacement  $\zeta$ , or its equivalent, at any point  $(x, y)$ , must satisfy the wave equation, namely,

$$\frac{\partial^2 \zeta}{\partial x^2} + \frac{\partial^2 \zeta}{\partial y^2} + k_1^2 \zeta = 0, \quad (1)$$

where  $k_1$  is a constant dependent upon the properties of the medium, and the pulsance of the disturbance therein. In problems pertaining to a rectangular boundary, e.g. a rectangular membrane, (1) is solved in the form given, subject to the particular boundary conditions imposed. If the boundary is circular or elliptical in shape, it is expedient, prior to solution, to transform (1) to either polar or elliptical coordinates, as the case may be.

**9.11. Elliptical coordinates.** We write  $x+iy = h \cosh(\xi+i\eta)$ , so that, equating real and imaginary parts,  $x = h \cosh \xi \cos \eta$ ,  $y = h \sinh \xi \sin \eta$ . Thus

$$\frac{x^2}{h^2 \cosh^2 \xi} + \frac{y^2}{h^2 \sinh^2 \xi} = \cos^2 \eta + \sin^2 \eta = 1, \quad (1)$$

and 
$$\frac{x^2}{h^2 \cos^2 \eta} - \frac{y^2}{h^2 \sin^2 \eta} = \cosh^2 \xi - \sinh^2 \xi = 1. \quad (2)$$

Then (1) represents a family of confocal ellipses with major axes  $2h \cosh \xi$ , minor axes  $2h \sinh \xi$ , the common foci being the points  $x = \pm h, y = 0$ . Also (2) represents a family of confocal hyperbolas with the same foci, as illustrated in Fig. 16 A. The two families of conics intersect orthogonally, and each intersection corresponds to a point defined by the coordinates  $x = h \cosh \xi \cos \eta$ ,  $y = h \sinh \xi \sin \eta$ . The angle  $\eta$  varies from 0 to  $2\pi$  in passing once round an ellipse, while if we consider a stretched elastic membrane clamped between two similar elliptical rings,  $\xi$  varies from zero along the line of foci to  $\xi_0$  at the rings.

At the extremities of the major axis of any confocal ellipse (Fig. 16 A),  $\eta = 0, \pi, y = 0$ , and  $x = \pm h \cosh \xi = \pm a$ . At the ends of the minor axis,  $\eta = \frac{1}{2}\pi, \frac{3}{2}\pi, x = 0$ , and  $y = \pm h \sinh \xi = \pm b$ . If  $e$  is

the eccentricity of the ellipse,  $h = ae$ , so  $\cosh \xi = e^{-1}$ , and when  $e \rightarrow 1$ ,  $\xi \rightarrow 0$ , while  $a \rightarrow h$ . Thus a long elliptical cylinder degenerates to a ribbon of equal length, whose width is  $2h$ , i.e. the interfocal

FIG. 16. (A) Orthogonally intersecting confocal ellipses and hyperbolas for elliptical coordinates.  $P$  has elliptical coordinates  $\xi = 2$ ,  $\eta = \frac{1}{3}\pi$  ( $60^\circ$ ), and cartesian coordinates  $x = h \cosh 2 \cos \frac{1}{3}\pi$ ,  $y = h \sinh 2 \sin \frac{1}{3}\pi$ .

(B) Degenerate form of ellipse when  $e = 1$ . As  $e \rightarrow 1$ ,  $a \rightarrow h$ ,  $b \rightarrow 0$  and the ellipse  $\rightarrow$  the interfocal line of length  $2h$ .

(C) Degenerate form of ellipse, when eccentricity  $e = 0$ . The foci coalesce at the centre of a circle radius  $r$ , equal to the semi-major axis. The original hyperbola through  $P$  (see A) is now radii making  $\phi = \pm \frac{1}{3}\pi$  with  $X'OX$ .

distance (see Fig. 16B). With  $a$  constant, if  $e \rightarrow 0$ ,  $\xi \rightarrow \infty$ , and the ellipse tends to a circle of radius  $a$ . Since  $h = ae$ ,  $h \rightarrow 0$ , the foci

tend to coalesce at the origin, and  $h \cosh \xi \rightarrow h \sinh \xi \rightarrow a$ . If  $h$  be constant, as  $a \rightarrow \infty$ ,  $\xi \rightarrow \infty$ , and  $e \rightarrow 0$ , so that the confocal ellipses tend to become concentric circles. Now (2) may be written

$$\frac{x^2}{\cos^2 \eta} - \frac{y^2}{\sin^2 \eta} = h^2. \quad (3)$$

As  $h \rightarrow 0$ ,  $y/x \rightarrow \pm \tan \eta$ , so  $\eta \rightarrow \phi$ ,  $\cos \eta \rightarrow \cos \phi$ , the confocal hyperbolas ultimately become radii of the circle and make angles  $\phi$  with the  $X$ -axis, as in Fig. 16 c.

FIG. 17. (A) Hyperbolic ( $ds_1$ ), elliptic ( $ds_2$ ) arc length, and radius vector  $r$ . (B) Area ( $ds_1 ds_2$ ) enclosed by two contiguous pairs of orthogonally intersecting confocal ellipses and hyperbolas.

**9.12. Arc lengths  $ds_1$ ,  $ds_2$ , and radius vector  $r$ .** Referring to Fig. 17, the hyperbolic and elliptic arc lengths are, respectively,

$$ds_1 = [(\partial x / \partial \xi)^2 + (\partial y / \partial \xi)^2]^{\frac{1}{2}} d\xi \quad (1)$$

and

$$ds_2 = [(\partial x / \partial \eta)^2 + (\partial y / \partial \eta)^2]^{\frac{1}{2}} d\eta. \quad (2)$$

Now

$$\begin{aligned} \partial x / \partial \xi &= h \sinh \xi \cos \eta, & \partial y / \partial \xi &= h \cosh \xi \sin \eta, \\ \partial x / \partial \eta &= -h \cosh \xi \sin \eta, & \partial y / \partial \eta &= h \sinh \xi \cos \eta, \end{aligned}$$

so each bracketed member in (1), (2) is

$$l_1 = h[\cosh^2 \xi \sin^2 \eta + \sinh^2 \xi \cos^2 \eta]^{\frac{1}{2}} = h(\cosh^2 \xi - \cos^2 \eta)^{\frac{1}{2}} \quad (3)$$

$$= \frac{h}{2^{\frac{1}{2}}} (\cosh 2\xi - \cos 2\eta)^{\frac{1}{2}}. \quad (4)$$

Hence from (1)–(3) we obtain

$$ds_1 = l_1 d\xi \quad \text{and} \quad ds_2 = l_1 d\eta. \quad (5)$$

Since  $ds_1$  is along the direction of the normal to the ellipse, we may write

$$dn = l_1 d\xi. \quad (6)$$

The distance of any point  $(x, y)$  from the origin, expressed in elliptical coordinates, is

$$r = (x^2 + y^2)^{\frac{1}{2}} = h[\cosh^2 \xi \cos^2 \eta + \sinh^2 \xi \sin^2 \eta]^{\frac{1}{2}} = h(\cosh^2 \xi - \sin^2 \eta)^{\frac{1}{2}} \quad (7)$$

$$= \frac{h}{2^{\frac{1}{2}}} (\cosh 2\xi + \cos 2\eta)^{\frac{1}{2}}. \quad (8)$$

When  $\xi$  is large enough,  $\cosh \xi \sim \sinh \xi \sim \frac{1}{2}e^{\xi}$ , so by (3), (7) with  $h$  constant,  $l_1 \sim h \cosh \xi \sim h \sinh \xi \sim r$  the radius vector. Hence we may write

$$ds_1 \sim r d\xi \sim dr; \quad ds_2 \sim r d\eta; \quad ds_1 ds_2 \sim r dr d\eta. \quad (9)$$

### 9.20. Transformation of (1) § 9.10 to elliptical coordinates.

Write  $z = x + iy = h \cosh(\xi + i\eta)$ ,  $\bar{z} = x - iy = h \cosh(\xi - i\eta)$ , then  $z\bar{z} = x^2 + y^2$ , and

$$\frac{4\partial^2 z\bar{z}}{\partial z \partial \bar{z}} = \left( \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} \right) z\bar{z}. \quad (1)$$

Putting  $\zeta = \xi + i\eta$ ,  $\bar{\zeta} = \xi - i\eta$ , we get  $z = h \cosh \zeta$ ,  $\bar{z} = h \cosh \bar{\zeta}$ , and  $\zeta\bar{\zeta} = \xi^2 + \eta^2$ . Thus

$$\frac{\partial \zeta}{\partial z} = \frac{1}{h \sinh \zeta}, \quad \frac{\partial \bar{\zeta}}{\partial \bar{z}} = \frac{1}{h \sinh \bar{\zeta}}, \quad \frac{4\partial^2 \zeta \bar{\zeta}}{\partial \zeta \partial \bar{\zeta}} = \left( \frac{\partial^2}{\partial \xi^2} + \frac{\partial^2}{\partial \eta^2} \right) \zeta \bar{\zeta},$$

so

$$\frac{\partial}{\partial z} = \frac{1}{h \sinh \zeta} \frac{\partial}{\partial \zeta}, \quad \frac{\partial}{\partial \bar{z}} = \frac{1}{h \sinh \bar{\zeta}} \frac{\partial}{\partial \bar{\zeta}}, \quad \text{and} \quad \frac{4\partial^2}{\partial \zeta \partial \bar{\zeta}} = \frac{\partial^2}{\partial \xi^2} + \frac{\partial^2}{\partial \eta^2}.$$

$$\text{Hence} \quad \frac{4\partial^2}{\partial z \partial \bar{z}} = \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} = \frac{4}{h^2 \sinh \zeta \sinh \bar{\zeta}} \frac{\partial^2}{\partial \zeta \partial \bar{\zeta}}, \quad (2)$$

$$\text{or} \quad \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} = \frac{2}{h^2 (\cosh 2\xi - \cos 2\eta)} \left( \frac{\partial^2}{\partial \xi^2} + \frac{\partial^2}{\partial \eta^2} \right). \quad (3)$$

Applying (3) to (1) § 9.10 leads to the equation

$$\frac{\partial^2 \zeta}{\partial \xi^2} + \frac{\partial^2 \zeta}{\partial \eta^2} + 2k^2 (\cosh 2\xi - \cos 2\eta) \zeta = 0, \quad (4)$$

with  $2k = k_1 h$ . Then (4) is the two-dimensional wave equation (1) § 9.10 expressed in elliptical coordinates.

**9.21. Solution of (4) § 9.20.** Let the desired form of solution be  $\zeta(\xi, \eta) = \psi(\xi)\phi(\eta)$ , where  $\psi$  is a function of  $\xi$  alone, and  $\phi$  a function of  $\eta$  alone. Then we obtain

$$\phi \frac{d^2 \psi}{d\xi^2} + \psi \frac{d^2 \phi}{d\eta^2} + 2k^2 (\cosh 2\xi - \cos 2\eta) \psi \phi = 0. \quad (1)$$

Dividing throughout by  $\psi\phi$  and rearranging leads to

$$\frac{1}{\psi} \frac{d^2\psi}{d\xi^2} + 2k^2 \cosh 2\xi = -\frac{1}{\phi} \frac{d^2\phi}{d\eta^2} + 2k^2 \cos 2\eta. \quad (2)$$

Since the l.h.s. is independent of  $\eta$ , and the r.h.s. of  $\xi$ , each side must be a constant, say  $a$ . Accordingly we obtain the two ordinary equations

$$\frac{d^2\phi}{d\eta^2} + (a - 2k^2 \cos 2\eta)\phi = 0 \quad (3)$$

$$\text{and} \quad \frac{d^2\psi}{d\xi^2} - (a - 2k^2 \cosh 2\xi)\psi = 0, \quad (4)$$

where  $a$  is the separation constant.† Then (3), (4) are the canonical forms with which we have dealt hitherto, and the above analysis illustrates the genesis of the equations which bear Mathieu's name. If in (3) we write  $\pm i\xi$  for  $\eta$ , it is transformed into (4), while the latter is transformed into (3) if  $\pm i\eta$  be written for  $\xi$ .

**9.30. Integral order solutions of (1) § 9.21.** A solution comprises the product of any two functions which are solutions of (3), (4) § 9.21, respectively, *for the same values of  $a$  and  $q$* . Since  $a$  may have *any* value, the number of solutions is unlimited. In practical applications the appropriate solutions are usually given by ordinary and modified Mathieu functions of *integral order*, i.e. solutions of (3), (4) § 9.21 corresponding to  $a = a_m, b_m$ . The solutions

TABLE 10. *Solutions of (1) § 9.21 when  $a$  has values for Mathieu functions of integral order.  $q > 0$*

$\zeta = \psi_m(\xi)\phi_m(\eta)$ for $a = a_m$	Property	$\zeta = \psi_m(\xi)\phi_m(\eta)$ for $a = b_m$	Property
$Ce_m(\xi, q)ce_m(\eta, q)$	Period $\pi$ or $2\pi$ in $\eta$ , $m$ even or odd	$Se_m(\xi, q)se_m(\eta, q)$	As in column 2.
$Fe_m(\xi, q)ce_m(\eta, q)$	Period $\pi i$ or $2\pi i$ in $\xi$ , $m$ even or odd	$Ge_m(\xi, q)se_m(\eta, q)$	
$Ce_m(\xi, q)fe_m(\eta, q)$	Period $\pi$ or $2\pi$ in $\eta$ , $m$ even or odd	$Se_m(\xi, q)ge_m(\eta, q)$	
$Fe_m(\xi, q)fe_m(\eta, q)$	Non-periodic in $\xi$	$Ge_m(\xi, q)ge_m(\eta, q)$	
	Non-periodic in $\eta$		
	Period $\pi i$ or $2\pi i$ in $\xi$ , $m$ even or odd		
	Non-periodic in $\eta$ , $\xi$		
$m = 0, 1, 2, \dots$		$m = 1, 2, 3, \dots$	

† This must not be confused with the semi-major axis of the ellipse.

$\phi(\eta) = ce_m(\eta, q)$  or  $se_m(\eta, q)$  with  $a, q$  real are important by virtue of their periodicity in  $\pi, 2\pi$ , and single-valuedness. Various product pairs, including second solutions of (3), (4) § 9.21, i.e. ordinary and modified Mathieu functions of the second kind, are set out in Table 10.

When  $q < 0$ , the solutions in Table 10 are valid provided the definitions of the various functions in Chapters II. VII are used.

*Alternative solutions.* As shown in Chapter VIII, there are alternative second solutions of equation (4) § 9.21. These are set out in Table 11. (See Chapter XIII also.)

TABLE 11. *Alternative second solutions of (1) § 9.21*

<i>Solution</i>	<i>Alternative solution</i>	<i>Defined at</i>	<i>Solution</i>	<i>Alternative solution</i>	<i>Defined at</i>

	$Fek_m(\xi, q)$	§ 8.14		$Fek_m(\xi, -q)$	..
$Ge_m(\xi, q)$	$Gey_m(\xi, q)$	§ 8.13	$Ge_m(\xi, -q)$	$Gey_m(\xi, -q)$	..
	$Gek_m(\xi, q)$	§ 8.14		$Gek_m(\xi, -q)$	..

**9.31. Solutions of (1) § 9.21 of real fractional order.** When  $(a, q)$  lies on an iso- $\beta$  curve in Fig. 11 the order of the solution is  $\nu = m + \beta$ ,  $0 < \beta < 1$ , and the solutions of (3), (4) § 9.21 coexist for  $a = a_{m+\beta}$ . Then the solutions of (1) § 9.21 are as shown in Table 12. Definitions of the various functions are given in §§ 4.71, 4.76.

TABLE 12. *Solutions of (1) § 9.21 when  $a = a_{m+\beta}$  for Mathieu functions of real fractional order  $\nu = m + \beta$ , and  $q$  is positive*

$\xi = \psi_\nu(\xi)\phi_\nu(\eta)$ for $a = a_\nu$	<i>Property of solutions</i>
$Ce_\nu(\xi, q)ce_\nu(\eta, q)$ $Se_\nu(\xi, q)ce_\nu(\eta, q)$ $Ce_\nu(\xi, q)se_\nu(\eta, q)$ $Se_\nu(\xi, q)se_\nu(\eta, q)$	If $\beta$ is a rational fraction $p/s$ in its lowest terms, $0 < p/s < 1$ , all solutions in $\eta$ have period $2s\pi$ , and in $\xi$ have period $2s\pi i$ . If $\beta$ is irrational, all solutions are non-periodic in $\eta, \xi$ .

When  $q$  is negative Table 12 is applicable provided appropriate definitions of the functions are used, e.g. in § 4.71. We omit consideration of solutions when  $(a, q)$  lies in an unstable region of Figs. 8, 11.

**9.40. Orthogonality theorem [135].** Let  $q_{n,m}$  be such that for  $n$  a positive integer and  $\xi = \xi_0$ ,  $\psi_n(\xi_0, q_{n,m}) = 0$ ,† where  $\psi_n$  is a solution of (4) § 9.21. Then if  $a, q$  are real, the point  $(a_{n,m}, q_{n,m})$  lies on

†  $q_{n,m}$  is a parametric zero of  $\psi_n$ : see §§ 12.40, 12.41.

the characteristic curve for the function  $\phi_n(\eta, q)$ , the latter being an integral-order solution of (3) §9.21. For instance, the curve  $a_2$  in Fig. 8 corresponds to  $ce_2(\eta, q)$  and also to  $Ce_2(\xi, q)$ . It follows that we may write

$$\frac{d^2\phi_n}{d\eta^2} + (a_{n,m} - 2q_{n,m} \cos 2\eta)\phi_n = 0 \quad (1)$$

and 
$$\frac{d^2\psi_n}{d\xi^2} - (a_{n,m} - 2q_{n,m} \cosh 2\xi)\psi_n = 0. \quad (2)$$

Put  $\zeta_{n,m} = \psi_n \phi_n$ , then for  $(a_{n,m}, q_{n,m})$  we have

$$\frac{\partial^2 \zeta_{n,m}}{\partial \xi^2} + \frac{\partial^2 \zeta_{n,m}}{\partial \eta^2} + 2q_{n,m}(\cosh 2\xi - \cos 2\eta)\zeta_{n,m} = 0. \quad (3)$$

Also for  $(a_{p,r}, q_{p,r})$

$$\frac{\partial^2 \zeta_{p,r}}{\partial \xi^2} + \frac{\partial^2 \zeta_{p,r}}{\partial \eta^2} + 2q_{p,r}(\cosh 2\xi - \cos 2\eta)\zeta_{p,r} = 0. \quad (4)$$

Multiplying (3) by  $\zeta_{p,r}$ , (4) by  $\zeta_{n,m}$ , and subtracting the second from the first we obtain

$$\begin{aligned} \frac{\partial}{\partial \xi} \left[ \zeta_{p,r} \frac{\partial \zeta_{n,m}}{\partial \xi} - \zeta_{n,m} \frac{\partial \zeta_{p,r}}{\partial \xi} \right] + \frac{\partial}{\partial \eta} \left[ \zeta_{p,r} \frac{\partial \zeta_{n,m}}{\partial \eta} - \zeta_{n,m} \frac{\partial \zeta_{p,r}}{\partial \eta} \right] + \\ + 2(q_{n,m} - q_{p,r})(\cosh 2\xi - \cos 2\eta)\zeta_{n,m} \zeta_{p,r} = 0. \end{aligned} \quad (5)$$

Integrating (5) with respect to  $\xi$  from 0 to  $\xi_0$ , and to  $\eta$  from 0 to  $2\pi$ , we get

$$\begin{aligned} \int_0^{2\pi} \left[ \zeta_{p,r} \frac{\partial \zeta_{n,m}}{\partial \xi} - \zeta_{n,m} \frac{\partial \zeta_{p,r}}{\partial \xi} \right]_0^{\xi_0} d\eta + \int_0^{\xi_0} \left[ \zeta_{p,r} \frac{\partial \zeta_{n,m}}{\partial \eta} - \zeta_{n,m} \frac{\partial \zeta_{p,r}}{\partial \eta} \right]_0^{2\pi} d\xi + \\ + 2(q_{n,m} - q_{p,r}) \int_0^{\xi_0} \int_0^{2\pi} (\cosh 2\xi - \cos 2\eta) \zeta_{n,m} \zeta_{p,r} d\xi d\eta = 0. \end{aligned} \quad (6)$$

If  $\zeta_{n,m} = Ce_{n,m} ce_{n,m}$  or  $Se_{n,m} se_{n,m}$ ,  $\zeta_{p,r} = Ce_{p,r} ce_{p,r}$  or  $Se_{p,r} se_{p,r}$ , the first integrand in (6) vanishes at  $\xi = 0, \xi_0$ , while the second vanishes by virtue of its periodicity in  $\eta$ . Hence it follows that the last integral is zero if  $p \neq n$ , i.e.

$$\int_0^{\xi_0} \int_0^{2\pi} (\cosh 2\xi - \cos 2\eta) \zeta_{n,m} \zeta_{p,r} d\xi d\eta = 0. \quad (7)$$

This holds also if  $p = n$ ,  $r \neq m$ . If  $p = n$  and  $r = m$ , the double integral does not vanish. Then we have

$$\int_0^{\xi} \int_0^{2\pi} \left\{ \frac{\text{Ce}_{n,m}^2(\xi) \text{ce}_{n,m}^2(\eta)}{\text{Se}_{n,m}^2(\xi) \text{se}_{n,m}^2(\eta)} \right\} (\cosh 2\xi - \cos 2\eta) d\xi d\eta \neq 0. \quad (8)$$

It may be remarked that if  $\phi_n = \text{ce}_{n,m}$  or  $\text{se}_{n,m}$ , these functions do not satisfy the *usual* orthogonal relations (§ 2.19) since  $\text{ce}_{n,m}$ ,  $\text{ce}_{p,r}$  have different  $q$  values, as also have  $\text{se}_{n,m}$ ,  $\text{se}_{p,r}$ ,  $n \neq p$ ,  $m \neq r$ .

The  $\eta$  integrals in (8) may be evaluated by aid of the following formulae:

$$\frac{1}{\pi} \int_0^{2\pi} \text{ce}_{2n}^2(\eta) \cos 2\eta d\eta = A_0^{(2n)} A_2^{(2n)} + \sum_{r=0}^{\infty} A_{2r}^{(2n)} A_{2r+2}^{(2n)} = \Theta_{2n}, \quad (9)$$

$$\frac{1}{\pi} \int_0^{2\pi} \text{ce}_{2n+1}^2(\eta) \cos 2\eta d\eta = \frac{1}{2} [A_1^{(2n+1)}]^2 + \sum_{r=0}^{\infty} A_{2r+1}^{(2n+1)} A_{2r+3}^{(2n+1)} = \Theta_{2n+1}, \quad (10)$$

$$\frac{1}{\pi} \int_0^{2\pi} \text{se}_{2n+1}^2(\eta) \cos 2\eta d\eta = -\frac{1}{2} [B_1^{(2n+1)}]^2 + \sum_{r=0}^{\infty} B_{2r+1}^{(2n+1)} B_{2r+3}^{(2n+1)} = \Psi_{2n+1}, \quad (11)$$

$$\frac{1}{\pi} \int_0^{2\pi} \text{se}_{2n+2}^2(\eta) \cos 2\eta d\eta = \sum_{r=0}^{\infty} B_{2r+2}^{(2n+2)} B_{2r+4}^{(2n+2)} = \Psi_{2n+2}. \quad (12)$$

Those parts of the  $\xi$  integrals involving  $\cosh 2\xi$  may be expressed in terms of derivatives by aid of (7) § 14.21.

# X

## INTEGRAL EQUATIONS AND RELATIONS

**10.10. Definition.** The equation

$$y(z) = \lambda \int_a^b \chi(u, z) y(u) du, \quad (1)$$

in which  $\chi(u, z)$  is a known function of the variables  $u, z$ , and  $\lambda$  a particular constant, is called a homogeneous linear integral equation for the unknown function  $y(u)$ .  $\chi(u, z)$  is termed the nucleus or kernel, and it is symmetrical if  $\chi(u, z) = \chi(z, u)$ , e.g.  $e^{-uz} = e^{-zu}$ . The equation has a continuous solution only for a discrete set of values of  $\lambda$ . These are called the characteristic values of the nucleus. The nuclei with which we shall deal herein are continuous and symmetrical in  $u, z$ , except in § 10.30 et seq.

**THEOREM.** Let

1°.  $\phi(u), \phi'(u), \phi''(u)$  be continuous with period  $\pi$  or  $2\pi$ , such that  $\phi'' + (a - 2k^2 \cos 2u)\phi = 0$ ;

2°.  $\chi(u, z), \chi'_{u,z}, \chi''_{u,z}$  be continuous in  $u, z$ , such that

$$(a) [\phi \chi'_u - \phi'_u \chi]_{u=0}^{u=2\pi} = 0,$$

$$(b) \frac{\partial^2 \chi}{\partial u^2} - \frac{\partial^2 \chi}{\partial z^2} - 2k^2(\cos 2u - \cos 2z)\chi = 0, \dagger$$

then 
$$y(z) = \lambda \int_0^{2\pi} \chi(u, z) \phi(u) du \quad (1)$$

satisfies Mathieu's equation.

*Proof.* By (1)

$$\frac{d^2 y}{dz^2} + (a - 2k^2 \cos 2z)y = \lambda \int_0^{2\pi} \left[ \frac{\partial^2 \chi}{\partial z^2} - (2k^2 \cos 2z)\chi \right] \phi du + \lambda a \int_0^{2\pi} \chi \phi du \quad (2)$$

$$= \lambda \int_0^{2\pi} \frac{\partial^2 \chi}{\partial u^2} \phi du + \lambda \int_0^{2\pi} (a - 2k^2 \cos 2u) \chi \phi du \quad (3)$$

† This is the wave equation  $\frac{\partial^2 \chi}{\partial u^2} + \frac{\partial^2 \chi}{\partial z^2} + 2k^2(\cosh 2u - \cos 2z)\chi = 0$  expressed in the modified elliptical coordinates  $x = h \cos u \cos z, y = ih \sin u \sin z$ , i.e.  $iu$  is written for  $u$ .

by 2° (b). Now

$$\int_0^{2\pi} \phi \frac{\partial^2 \chi}{\partial u^2} du = \int_0^{2\pi} \phi d(\chi'_u) = [\phi \chi'_u]_0^{2\pi} - \int_0^{2\pi} \phi' d\chi \quad (4)$$

$$= [\phi \chi'_u - \phi'_u \chi]_0^{2\pi} + \int_0^{2\pi} \phi'' \chi du. \quad (5)$$

By hypothesis [ ] vanishes, so

$$\int_0^{2\pi} \phi \frac{\partial^2 \chi}{\partial u^2} du = \int_0^{2\pi} \frac{\partial^2 \phi}{\partial u^2} \chi du. \quad (6)$$

Substituting from (6) into the r.h.s. of (3) leads to

$$\begin{aligned} \frac{d^2 y}{dz^2} + (a - 2k^2 \cos 2z)y &= \lambda \int_0^{2\pi} \left[ \frac{d^2 \phi}{du^2} + (a - 2k^2 \cos 2u)\phi \right] \chi du \\ &= 0, \quad \text{by hypothesis.} \end{aligned} \quad (7)$$

Hence  $y(z)$  satisfies Mathieu's equation.

If  $\chi(u, z)$  is periodic in  $u, z$ , with period  $\pi, 2\pi$ ,  $y(u)$  has the same period as  $\phi(u)$ , so  $\phi(u) = \lambda_0 y(u)$ . Accordingly we have the homogeneous linear integral equation of the first kind for the periodic functions  $\text{ce}_m(z, q)$ ,  $\text{se}_m(z, q)$ , namely,

$$y(z) = \lambda_0 \int_0^{2\pi} \chi(u, z) y(u) du. \quad (8)$$

If  $[\phi \chi'_u - \phi'_u \chi]_0^{2\pi} = 0$ , the upper limit in (8) may be  $\pi$ .

The theorem is valid for  $\text{Ce}_m(z, q)$ ,  $\text{Se}_m(z, q)$  if for  $z$  we write  $iz$  in (1), so that  $y$  satisfies  $y'' - (a - 2k^2 \cosh 2z)y = 0$ .

**10.11. The eight primary nuclei for  $\text{ce}_m(z, q)$ ,  $\text{se}_m(z, q)$ .** We commence with the wave equation

$$\frac{\partial^2 \chi}{\partial x^2} + \frac{\partial^2 \chi}{\partial y^2} + k_1^2 \chi = 0, \quad (1)$$

where  $k_1 h = 2k$ . By substitution we confirm that simple solutions are:  $\chi = e^{ik_1 x}$ ,  $e^{ik_1 y}$ ,  $y e^{ik_1 x}$ , and  $x e^{ik_1 y}$ . The real and imaginary parts of these functions are separate solutions, so we obtain the eight given in Table 13.

TABLE 13

<i>Solutions of (1)</i>	
$\cos k_1 x$	$\cos k_1 y$
$\sin k_1 x$	$x \cos k_1 y$
$\sin k_1 y$	$y \cos k_1 x$
$y \sin k_1 x$	$x \sin k_1 y$

In modified elliptical coordinates,  $x = h \cos u \cos z$ ,  $y = ih \sin u \sin z$ , and by § 9.20, (1) may be transformed to

$$\frac{\partial^2 \chi}{\partial u^2} - \frac{\partial^2 \chi}{\partial z^2} - 2k^2(\cos 2u - \cos 2z)\chi = 0, \quad (2)$$

which is (b) 2° § 10.10. Substituting for  $x, y$  from above in Table 13 and omitting the multiplier  $i$ , we obtain eight primary solutions of (2). These are the eight primary nuclei  $\chi(u, z)$ , and they may be used in (8) § 10.10 with the upper limit  $\pi$ . They are set out in Table 14.

TABLE 14. *The eight primary nuclei for  $ce_m(z, q)$ ,  $se_m(z, q)$ ,  $q > 0$* 

$\chi(u, z) = \text{nucleus of (8) § 10.10, and a solution of (2)}$						$y(z)$
1	$\cos(2k \cos u \cos z)$	$\lambda_{2n}$	1'	$\cosh(2k \sin u \sin z)$	$\lambda'_{2n}$	$ce_{2n}(z, q)$
2	$\sin(2k \cos u \cos z)$	$\lambda_{2n+1}$	2'	$\cos u \cos z \times$ $\times \cosh(2k \sin u \sin z)$	$\lambda'_{2n+1}$	$ce_{2n+1}(z, q)$
3	$\sinh(2k \sin u \sin z)$	$\mu_{2n+1}$	3'	$\sin u \sin z \times$ $\times \cos(2k \cos u \cos z)$	$\mu'_{2n+1}$	$se_{2n+1}(z, q)$
4	$\sin u \sin z \times$ $\times \sin(2k \cos u \cos z)$	$\mu_{2n+2}$	4'	$\cos u \cos z \times$ $\times \sinh(2k \sin u \sin z)$	$\mu'_{2n+2}$	$se_{2n+2}(z, q)$

Each nucleus in Table 14 is symmetrical and periodic in  $u, z$ . (1), (4) have period  $\pi$ , while (2), (3) have period  $2\pi$ . The functions  $y(z)$  are allocated to their respective nuclei by considering periodicity, evenness, and oddness. Since  $ce_m(z, q)$ ,  $se_m(z, q)$  satisfy a homogeneous linear integral equation with a symmetrical nucleus, it follows that they are orthogonal [215] (see also § 2.19).

We have now to derive the characteristic values  $\lambda_m, \mu_m$  corresponding to various nuclei. This may be effected by aid of Bessel series for the Mathieu functions, as shown hereafter.

**10.12. Bessel function expansions.** Inserting nucleus 1 Table 14, § 10.11 and  $ce_{2n}(u, q)$  in (8) § 10.10, with limits 0,  $\pi$ , we get

$$ce_{2n}(z, q) = \lambda_{2n} \int_0^\pi \cos(2k \cos u \cos z) ce_{2n}(u) du \quad (a_{2n}). \quad (1)$$

Substituting the expansions of the circular [202, p. 43] and Mathieu functions, (1) becomes

$$\begin{aligned} \text{ce}_{2n}(z, q) = \lambda_{2n} \int_0^\pi \left[ J_0(2k \cos z) + 2 \sum_{r=1}^{\infty} (-1)^r J_{2r}(2k \cos z) \cos 2ru \right] \times \\ \times \sum_{s=0}^{\infty} A_{2s}^{(2n)} \cos 2su \, du. \quad (2) \end{aligned}$$

Consider any  $r$  in the first  $\Sigma$ . By virtue of orthogonality of the circular functions, all integrals vanish save when  $r = s$ . Thus we get

$$\begin{aligned} (-1)^r 2\lambda_{2n} J_{2r}(2k \cos z) A_{2r}^{(2n)} \int_0^\pi \cos^2 2ru \, du \\ = (-1)^r \lambda_{2n} \pi A_{2r}^{(2n)} J_{2r}(2k \cos z). \quad (3) \end{aligned}$$

Hence the expansion of the Mathieu function in B.F. is

$$\text{ce}_{2n}(z, q) = \lambda_{2n} \pi \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} J_{2r}(2k \cos z). \quad (4)$$

By 2° § 8.50, the r.h.s. of (4) is absolutely and uniformly convergent in any closed rectangle of the  $z$ -plane,  $k^2$  real  $> 0$ . Since the r.h.s. represents  $\text{ce}_{2n}(z, q)$ , it and also (1) is a solution of

$$y'' + (a - 2q \cos 2z)y = 0,$$

$q > 0$ ,  $a = a_{2n}$ . This remark applies as well to the integral equations and their expansions for  $\text{ce}_{2n+1}(z, q)$ ,  $\text{se}_m(z, q)$ , with  $q > 0$ ,  $a = a_{2n+1}$ ,  $b_m$ , respectively, given in later sections.

*Determination of  $\lambda_{2n}$ .* In (4) put  $z = \frac{1}{2}\pi$ , then  $\cos z = 0$ , and all the  $J$  vanish except  $J_0(0) = 1$ . Therefore

$$\lambda_{2n} = \text{ce}_{2n}(\tfrac{1}{2}\pi, q) / \pi A_0^{(2n)} = \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} / \pi A_0^{(2n)}, \quad (5)$$

so  $\lambda_{2n}$  is a function of  $q$ . Using the tabular values of the  $A$ , we have for  $n = 2$ ,  $q = 8$ ,

$$\begin{aligned} \text{ce}_4(\tfrac{1}{2}\pi, 8) \simeq \sum_{r=0}^8 (-1)^r A_{2r}^{(4)} = 0.24703 \, 39 - 0.59450 \, 88 + \\ + 0.63941 \, 57 + 0.33453 \, 00 + 0.06089 \, 34 + 0.00607 \, 17 + \\ + 0.00039 \, 05 + 0.00001 \, 77 + 0.00000 \, 06 \\ = 0.69384 \, 47. \dagger \quad (6) \end{aligned}$$

Hence by (5), (6) we get

$$\lambda_4 = 0.69384 \, 47 / \pi \times 0.24703 \, 39 = 0.89275... \quad (7)$$

when  $q = 8$ .

† This may be obtained from [95] to five decimal places.

**10.13. Exponential nucleus.** We shall now demonstrate that

$$\text{ce}_{2n}(z, q) = \lambda_{2n} \int_0^\pi e^{2ik \cos u \cos z} \text{ce}_{2n}(u) du \quad (a_{2n}). \quad (1)$$

To do so, we merely need to prove that its imaginary part vanishes, since by (1) § 10.12 its real part represents  $\text{ce}_{2n}(z, q)$ . Then

$$\text{Imag. part} = \lambda_{2n} \int_0^\pi 2 \sum_{m=0}^{\infty} (-1)^m J_{2m+1}(2k \cos z) \cos(2m+1)u \text{ce}_{2n}(u) du, \quad (2)$$

and this vanishes by virtue of the orthogonality of the circular functions. In the same way it may be shown that integral equations in the sections below can have exponential nuclei. Either the real or the imaginary part of the integral vanishes, as the case may be.

**10.14. Bessel series for  $\text{ce}_{2n+1}(z, q)$ .** Using this function and nucleus 2, Table 14, § 10.11 in (8) § 10.10, a repetition of the analysis in § 10.12 yields

$$\text{ce}_{2n+1}(z, q) = \lambda_{2n+1} \pi \sum_{r=0}^{\infty} (-1)^r A_{2r+1}^{(2n+1)} J_{2r+1}(2k \cos z) \quad (a_{2n+1}). \quad (1)$$

By 2° § 8.50 this series is absolutely and uniformly convergent in any closed rectangle of the  $z$ -plane,  $k^2$  real  $> 0$ , as also is its first derivative. Consequently term-by-term differentiation is permissible, so

$$\begin{aligned} \text{ce}'_{2n+1}(z, q) &= -\lambda_{2n+1} 2\pi k \sin z \times \\ &\times \sum_{r=0}^{\infty} (-1)^r A_{2r+1}^{(2n+1)} [d J_{2r+1}(2k \cos z) / d(2k \cos z)]. \end{aligned} \quad (2)$$

Now  $J'_m(u) = \frac{1}{2}[J_{m-1}(u) - J_{m+1}(u)]$ , and since  $J_p(0) = 0$  if  $p \neq 0$ , when  $z = \frac{1}{2}\pi$ , the only non-zero term is  $\frac{1}{2}J_0(0) = \frac{1}{2}$ . Thus

$$\text{ce}'_{2n+1}(\tfrac{1}{2}\pi, q) = -\pi k A_1^{(2n+1)} \lambda_{2n+1}, \quad (3)$$

so

$$\lambda_{2n+1} = -\text{ce}'_{2n+1}(\tfrac{1}{2}\pi, q) / \pi k A_1^{(2n+1)} = \sum_{r=0}^{\infty} (-1)^r (2r+1) A_{2r+1}^{(2n+1)} / \pi k A_1^{(2n+1)}. \quad (4)$$

**10.15. Additional expansions.** Using nuclei 1', 3 from Table 14 § 10.11 and proceeding as in §§ 10.12, 10.14, we find that

$$\text{ce}_{2n}(z, q) = \lambda'_{2n} \pi \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} I_{2r}(2k \sin z) \quad (a_{2n}), \quad (1)$$

$$\text{with} \quad \lambda'_{2n} = \frac{1}{\pi A_0^{(2n)}} \sum_{r=0}^{\infty} A_{2r}^{(2n)} = \frac{ce_{2n}(0, q)}{\pi A_0^{(2n)}}; \quad (2)$$

$$se_{2n+1}(z, q) = \mu_{2n+1} \pi \sum_{r=0}^{\infty} (-1)^r B_{2r+1}^{(2n+1)} I_{2r+1}(2k \sin z) \quad (3)$$

$$\text{with} \quad \mu_{2n+1} = \frac{1}{\pi k B_1^{(2n+1)}} \sum_{r=0}^{\infty} (2r+1) B_{2r+1}^{(2n+1)} = \frac{se'_{2n+1}(0, q)}{\pi k B_1^{(2n+1)}}. \quad (4)$$

**10.16. Determination of  $\mu_{2n+2}$ ,  $\lambda'_{2n+1}$ ,  $\mu'_{2n+1}$ ,  $\mu'_{2n+2}$ .** If we select  $\mu_{2n+2}$ , the integral equation, using nucleus 4, Table 14, is

$$se_{2n+2}(z, q) = \mu_{2n+2} \int_0^{\pi} \sin u \sin z \sin(2k \cos u \cos z) \times \\ \times se_{2n+2}(u, q) du \quad (b_{2n+2}) \quad (1)$$

$$= 2\mu_{2n+2} \int_0^{\pi} \sin u \sin z \sum_{r=0}^{\infty} (-1)^r J_{2r+1}(2k \cos z) \cos(2r+1)u \times \\ \times \sum_{s=0}^{\infty} B_{2s+2}^{(2n+2)} \sin(2s+2)u du \quad (2)$$

$$= \mu_{2n+2} \int_0^{\pi} \sin z \sum_{r=0}^{\infty} (-1)^r J_{2r+1}(2k \cos z) \cos(2r+1)u \times \\ \times \sum_{s=0}^{\infty} B_{2s+2}^{(2n+2)} [\cos(2s+1)u - \cos(2s+3)u] du \quad (3)$$

$$= \mu_{2n+2} \frac{1}{2} \pi \sin z \times \\ \times \sum_{r=0}^{\infty} (-1)^r B_{2r+2}^{(2n+2)} [J_{2r+1}(2k \cos z) + J_{2r+3}(2k \cos z)]. \quad (4)$$

Now  $\left(\frac{2r+2}{u}\right) J_{2r+2}(u) = \frac{1}{2} [J_{2r+1}(u) + J_{2r+3}(u)]$ , so (4) takes the form

$$se_{2n+2}(z, q) = \mu_{2n+2} \frac{\pi \tan z}{2k} \sum_{r=0}^{\infty} (-1)^r (2r+2) B_{2r+2}^{(2n+2)} J_{2r+2}(2k \cos z). \quad (5)$$

This series and its first derivative is absolutely and uniformly convergent for all finite values of  $z$ ,  $k^2$  real  $> 0$ . Thus term-by-term differentiation with respect to  $z$  is valid and we get

$$se'_{2n+2}(z, q) = \mu_{2n+2} \frac{\pi}{2k} \left[ \sum_{r=0}^{\infty} (-1)^r (2r+2) B_{2r+2}^{(2n+2)} \{ \sec^2 z J_{2r+2}(2k \cos z) - \right. \\ \left. - k \tan z \sin z [J_{2r+1}(2k \cos z) - J_{2r+3}(2k \cos z)] \} \right]. \quad (6)$$

As  $z \rightarrow \frac{1}{2}\pi$  all terms vanish except  $\sec^2 z J_2(2k \cos z) \rightarrow \frac{1}{2}k^2$  and  $-k \tan z \sin z J_1(2k \cos z) \rightarrow -k^2$ . Hence

$$se'_{2n+2}(\frac{1}{2}\pi, q) = -\mu'_{2n+2} \frac{\pi}{2} k B_2^{(2n+2)}, \quad (7)$$

$$\text{so} \quad \mu'_{2n+2} = -2 se'_{2n+2}(\frac{1}{2}\pi, q) / \pi k B_2^{(2n+2)} \quad (8)$$

$$= \frac{2}{\pi k B_2^{(2n+2)}} \sum_{r=0}^{\infty} (-1)^r (2r+2) B_{2r+2}^{(2n+2)}. \quad (9)$$

For the remaining nuclei in Table 14 § 10.11, we obtain

$$ce_{2n+1}(z, q) = \lambda'_{2n+1} \frac{\pi \cot z}{2k} \times \sum_{r=0}^{\infty} (-1)^r (2r+1) A_{2r+1}^{(2n+1)} I_{2r+1}(2k \sin z) \quad (a_{2n+1}), \quad (10)$$

$$\text{with} \quad \lambda'_{2n+1} = \frac{2 ce_{2n+1}(0, q)}{\pi A_1^{(2n+1)}} = \frac{2}{\pi A_1^{(2n+1)}} \sum_{r=0}^{\infty} A_{2r+1}^{(2n+1)}. \quad (11)$$

$$se_{2n+1}(z, q) = \mu'_{2n+1} \frac{\pi \tan z}{2k} \times \sum_{r=0}^{\infty} (-1)^r (2r+1) B_{2r+1}^{(2n+1)} J_{2r+1}(2k \cos z) \quad (b_{2n+1}), \quad (12)$$

$$\text{with} \quad \mu'_{2n+1} = \frac{2 se_{2n+1}(\frac{1}{2}\pi, q)}{\pi B_1^{(2n+1)}} = \frac{2}{\pi B_1^{(2n+1)}} \sum_{r=0}^{\infty} (-1)^r B_{2r+1}^{(2n+1)}. \quad (13)$$

$$se_{2n+2}(z, q) = \mu'_{2n+2} \frac{\pi \cot z}{2k} \times \sum_{r=0}^{\infty} (-1)^r (2r+2) B_{2r+2}^{(2n+2)} I_{2r+2}(2k \sin z) \quad (b_{2n+2}), \quad (14)$$

$$\text{with} \quad \mu'_{2n+2} = \frac{2 se'_{2n+2}(0, q)}{\pi k B_2^{(2n+2)}} = \frac{2}{\pi k B_2^{(2n+2)}} \sum_{r=0}^{\infty} (2r+2) B_{2r+2}^{(2n+2)}. \quad (15)$$

By 2° § 8.50 all series in § 10.15 and the present section are absolutely and uniformly convergent in any closed rectangle of the  $z$ -plane,  $k^2 = q$  real  $> 0$ .

The characteristic values in Table 15 are expressed in terms of the coefficients in the series for the corresponding Mathieu functions. By § 3.21 the sigma terms are absolutely convergent in  $0 \leq q \leq q_0$ . By § 3.25 the  $A, B$  are continuous functions of  $q$ , and by § 3.30  $A_0^{(2n)}, A_1^{(2n+1)}, B_1^{(2n+1)}, B_2^{(2n+2)}$  have no zeros in  $q > 0$ , but tend to zero monotonically as  $q \rightarrow +\infty$ .  $\lambda_0, \lambda'_0 \rightarrow 1/\pi$  and  $\lambda'_1, \mu'_1 \rightarrow 2/\pi$  as  $q \rightarrow 0$ , and are continuous in  $0 \leq q \leq q_0$ . For  $n > 0$ ,  $\lambda_{2n}, \lambda'_{2n}, \lambda'_{2n+1}, \mu'_{2n+1}$ ,

TABLE 15. *Characteristic values for the nuclei in Table 14*

$\lambda_{2n} = \frac{ce_{2n}(\frac{1}{2}\pi, q)}{\pi A_0^{(2n)}}$ $= \frac{\sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)}}{\pi A_0^{(2n)}}$	$\lambda'_{2n} = \frac{ce_{2n}(0, q)}{\pi A_0^{(2n)}}$ $= \frac{\sum_{r=0}^{\infty} A_{2r}^{(2n)}}{\pi A_0^{(2n)}}$	$ce_{2n}(z, q)$
$\lambda_{2n+1} = -\frac{ce'_{2n+1}(\frac{1}{2}\pi, q)}{\pi k A_1^{(2n+1)}}$ $= \frac{\sum_{r=0}^{\infty} (-1)^r (2r+1) A_{2r+1}^{(2n+1)}}{\pi k A_1^{(2n+1)}}$	$\lambda'_{2n+1} = \frac{2 ce_{2n+1}(0, q)}{\pi A_1^{(2n+1)}}$ $= \frac{2 \sum_{r=0}^{\infty} A_{2r+1}^{(2n+1)}}{\pi A_1^{(2n+1)}}$	$ce_{2n+1}(z, q)$
$\mu_{2n+1} = \frac{se'_{2n+1}(0, q)}{\pi k B_1^{(2n+1)}}$ $= \frac{\sum_{r=0}^{\infty} (2r+1) B_{2r+1}^{(2n+1)}}{\pi k B_1^{(2n+1)}}$	$\mu'_{2n+1} = \frac{2 se_{2n+1}(\frac{1}{2}\pi, q)}{\pi B_1^{(2n+1)}}$ $= \frac{2 \sum_{r=0}^{\infty} (-1)^r B_{2r+1}^{(2n+1)}}{\pi B_1^{(2n+1)}}$	$se_{2n+1}(z, q)$
$\mu_{2n+2} = -\frac{2 se'_{2n+2}(\frac{1}{2}\pi, q)}{\pi k B_2^{(2n+2)}}$ $= \frac{2 \sum_{r=0}^{\infty} (-1)^r (2r+2) B_{2r+2}^{(2n+2)}}{\pi k B_2^{(2n+2)}}$	$\mu'_{2n+2} = \frac{2 se'_{2n+2}(0, q)}{\pi k B_2^{(2n+2)}}$ $= \frac{2 \sum_{r=0}^{\infty} (2r+2) B_{2r+2}^{(2n+2)}}{\pi k B_2^{(2n+2)}}$	$se_{2n+2}(z, q)$

and for  $n \geq 0$ ,  $\lambda_{2n+1}$ ,  $\mu_{2n+1}$ ,  $\mu_{2n+2}$ ,  $\mu'_{2n+2}$  are continuous,  $0 < q \leq q_0$ . The discontinuity in each of the first set at  $q = 0$  is due to vanishing of the coefficient in the denominator. That in each of the second set arises from the factor  $k^{-1} = q^{-1}$ , and for  $n > 0$  to vanishing of the coefficient in the denominator. The form of the latter may be derived from the general result (9) § 3.33. Thus as  $q \rightarrow 0$ , we obtain

$$A_0^{(2n)} \simeq q^n / 2^{2n-1} (2n)!; \quad B_2^{(2n+2)} \simeq (n+1) q^n / 2^{2n} (2n+1)!; \quad (16)$$

$$A_1^{(2n+1)} \simeq B_1^{(2n+1)} \simeq q^n / 2^{2n} (2n)! \quad (17)$$

The reciprocal of each coefficient has an infinity of order  $n$  at  $q = 0$ .

TABLE 16. *Illustrating behaviour of characteristic values as  $q \rightarrow 0$* 

Characteristic value	Behaviour as $q \rightarrow 0$	Characteristic value	Behaviour as $q \rightarrow 0$
$\lambda_{2n}$	$\rightarrow \infty, n > 0$	$\lambda'_{2n}$	$\rightarrow \infty, n > 0$
$\lambda_{2n+1}$	$\rightarrow \infty$	$\lambda'_{2n+1}$	$\rightarrow \infty, n > 0$
$\mu_{2n+1}$	$\rightarrow \infty$	$\mu_{2n+1}$	$\rightarrow \infty, n > 0$
$\mu_{2n+2}$	$\rightarrow \infty$	$\mu'_{2n+2}$	$\rightarrow \infty$

**10.17. Theorem on integral relations.** If  $y(u)$  is a Mathieu function of period  $\pi$  or  $2\pi$ ;  $\chi(u, z)$  the corresponding nucleus for the integral equation;  $\xi'_u(u, z) = \chi(u, z)$ , so that  $\xi(u, z) = \int_0^u \chi(u, z) du$  and  $[y(u)\xi(u, z)]_{u=0}^{u=\pi} = 0$ , then

$$y(z) = -\lambda \int_0^\pi \left[ \int_0^u \chi(u, z) du \right] y'(u) du. \quad (1)$$

*Proof.* Substituting for  $\chi$  into (8) § 10.10, we get

$$y(z)/\lambda = \int_0^\pi \xi'_u(u, z) y(u) du = \int_0^\pi y(u) d[\xi(u, z)]_u \quad (2)$$

$$= [y(u)\xi(u, z)]_{u=0}^{u=\pi} - \int_0^\pi \xi(u, z) y'(u) du, \quad (3)$$

so 
$$y(z) = -\lambda \int_0^\pi \left[ \int_0^u \chi(u, z) du \right] y'(u) du, \quad (4)$$

since the first member on the r.h.s. of (3) vanishes, by hypothesis.

**10.18. Example.** To illustrate the application of (4) § 10.17, we take nucleus 4 in Table 14 § 10.11, namely,

$$\chi(u, z) = \sin u \sin z \sin(2k \cos u \cos z)$$

with  $y(u) = \text{se}_{2n+2}(u, q)$ . Then

$$\xi(u, z) = \int_0^u \chi(u, z) du = -\frac{\tan z}{2k} \int_0^u \sin(2k \cos u \cos z) d(2k \cos u \cos z) \quad (1)$$

$$= \frac{\tan z}{2k} \cos(2k \cos u \cos z). \quad (2)$$

But  $[y(u)\xi(u, z)]_{u=0}^{u=\pi} = 0$ , so

$$\cot z \text{se}_{2n+2}(z, q) = -\frac{\lambda}{2k} \int_0^\pi \cos(2k \cos u \cos z) \text{se}'_{2n+2}(u) du \quad (3)$$

$$= -\frac{\lambda}{2k} \int_0^\pi \left[ J_0(2k \cos z) + 2 \sum_{r=0}^{\infty} (-1)^{r+1} J_{2r+2}(2k \cos z) \cos(2r+2)u \right] \times \\ \times \sum_{s=0}^{\infty} (2s+2) B_{2s+2}^{(2n+2)} \cos(2s+2)u du \quad (4)$$

$$= \frac{\pi\lambda}{2k} \sum_{r=0}^{\infty} (-1)^r (2r+2) B_{2r+2}^{(2n+2)} J_{2r+2}(2k \cos z). \quad (5)$$

Comparison with (5) § 10.16 shows that  $\lambda = \mu_{2n+2}$ , so from (3) and (1) § 10.16 we get

$$2k \int_0^\pi \sin u \cos z \sin(2k \cos u \cos z) \text{se}_{2n+2}(u, q) du \\ = - \int_0^\pi \cos(2k \cos u \cos z) \text{se}'_{2n+2}(u, q) du. \quad (6)$$

The integral relations given below may be derived by analysis akin to that above.

$$\tan z \text{ce}_{2n+1}(z, q) = -\frac{\lambda'_{2n+1}}{2k} \int_0^\pi \sinh(2k \sin u \sin z) \text{ce}'_{2n+1}(u, q) du, \quad (7)$$

$$\cot z \text{se}_{2n+1}(z, q) = \frac{\mu'_{2n+1}}{2k} \int_0^\pi \sin(2k \cos u \cos z) \text{se}'_{2n+1}(u, q) du, \quad (8)$$

$$\tan z \text{se}_{2n+2}(z, q) = -\frac{\mu'_{2n+2}}{2k} \int_0^\pi \cosh(2k \sin u \sin z) \text{se}'_{2n+2}(u, q) du. \quad (9)$$

**10.19. Formulae for  $\text{ce}_m(z, -q)$ ,  $\text{se}_m(z, -q)$ .** These functions are solutions of the equation  $y'' + (a + 2q \cos 2z)y = 0$ . Thus the required formulae may be derived from those in preceding sections by aid of § 2.18. The values of  $q$  and  $k$  remain as before, i.e.  $q > 0$ .

**10.20. Integral relations for  $\text{Ce}_m(z, q)$ ,  $\text{Se}_m(z, q)$ .** These are derived by applying the relationships in (2)–(5) § 2.30 to the integral equations for  $\text{ce}_m(z, q)$ ,  $\text{se}_m(z, q)$  in § 10.12 et seq. Thus

$$\text{Ce}_{2n}(z, q) \\ = \frac{\text{ce}_{2n}(\frac{1}{2}\pi, q)}{\pi A_0^{(2n)}} \int_0^\pi \cos(2k \cos u \cosh z) \text{ce}_{2n}(u, q) du \quad (1)$$

$$= \frac{\text{ce}_{2n}(0, q)}{\pi A_0^{(2n)}} \int_0^\pi \cos(2k \sin u \sinh z) \text{ce}_{2n}(u, q) du; \quad (2)$$

$$\text{Ce}_{2n+1}(z, q) \\ = -\frac{\text{ce}'_{2n+1}(\frac{1}{2}\pi, q)}{\pi k A_1^{(2n+1)}} \int_0^\pi \sin(2k \cos u \cosh z) \text{ce}_{2n+1}(u, q) du \quad (3)$$

$$= \frac{2 \text{ce}_{2n+1}(0, q)}{\pi A_1^{(2n+1)}} \int_0^\pi \cos u \cosh z \cos(2k \sin u \sinh z) \text{ce}_{2n+1}(u, q) du; \quad (4)$$

$$\text{Se}_{2n+1}(z, q)$$

$$= \frac{2 \text{se}_{2n+1}(\frac{1}{2}\pi, q)}{\pi B_1^{(2n+1)}} \int_0^\pi \sin u \sinh z \cos(2k \cos u \cosh z) \text{se}_{2n+1}(u, q) du \quad (5)$$

$$= \frac{\text{se}'_{2n+1}(0, q)}{\pi k B_1^{(2n+1)}} \int_0^\pi \sin(2k \sin u \sinh z) \text{se}_{2n+1}(u, q) du; \quad (6)$$

$$\text{Se}_{2n+2}(z, q)$$

$$= -\frac{2 \text{se}'_{2n+2}(\frac{1}{2}\pi, q)}{\pi k B_2^{(2n+2)}} \int_0^\pi \sin u \sinh z \sin(2k \cos u \cosh z) \text{se}_{2n+2}(u, q) du \quad (7)$$

$$= \frac{2 \text{se}'_{2n+2}(0, q)}{\pi k B_2^{(2n+2)}} \int_0^\pi \cos u \cosh z \sin(2k \sin u \sinh z) \text{se}_{2n+2}(u, q) du. \quad (8)$$

The evaluations of (1)–(8) are given at (15), (17) § 8.10; (1), (2) § 8.12; (6), (7), (10), (11) § 8.13, respectively. From § 10.18 and Table 15 § 10.16 additional relations in which  $\text{ce}'_{2n+1}$ ,  $\text{se}'_{2n+1}$ ,  $\text{se}'_{2n+2}$  appear under the integral sign may be written down. All the above representations of the modified Mathieu functions are first solutions of (1) § 2.30, provided  $a$  has its proper value.

**10.21. Integral relations for  $\text{Ce}_m(z, -q)$ ,  $\text{Se}_m(z, -q)$ .** These may be derived from (1)–(8) § 10.20 by applying the definitions (1), (11), (21), (31), § 8.30. Thus

$$\text{Ce}_{2n}(z, -q)$$

$$= \frac{(-1)^n \text{ce}_{2n}(\frac{1}{2}\pi, q)}{\pi A_0^{(2n)}} \int_0^\pi \cosh(2k \cos u \sinh z) \text{ce}_{2n}(u, q) du \quad (1)$$

$$= \frac{(-1)^n \text{ce}_{2n}(0, q)}{\pi A_0^{(2n)}} \int_0^\pi \cosh(2k \sin u \cosh z) \text{ce}_{2n}(u, q) du; \quad (2)$$

$$\text{Ce}_{2n+1}(z, -q)$$

$$= \frac{(-1)^n 2 \text{se}_{2n+1}(\frac{1}{2}\pi, q)}{\pi B_1^{(2n+1)}} \int_0^\pi \sin u \cosh z \cosh(2k \cos u \sinh z) \text{se}_{2n+1}(u, q) du \quad (3)$$

$$= \frac{(-1)^n \text{se}'_{2n+1}(0, q)}{\pi k B_1^{(2n+1)}} \int_0^\pi \sinh(2k \sin u \cosh z) \text{se}_{2n+1}(u, q) du; \quad (4)$$

$$\begin{aligned}
 & \text{Se}_{2n+1}(z, -q) \\
 &= \frac{(-1)^{n+1} \text{ce}'_{2n+1}(\frac{1}{2}\pi, q)}{\pi k A_1^{(2n+1)}} \int_0^\pi \sinh(2k \cos u \sinh z) \text{ce}_{2n+1}(u, q) du \quad (5) \\
 &= \frac{(-1)^n 2 \text{ce}_{2n+1}(0, q)}{\pi A_1^{(2n+1)}} \int_0^\pi \cos u \sinh z \cosh(2k \sin u \cosh z) \text{ce}_{2n+1}(u, q) du; \quad (6)
 \end{aligned}$$

$$\begin{aligned}
 & \text{Se}_{2n+2}(z, -q) \\
 &= \frac{(-1)^{n+1} 2 \text{se}'_{2n+2}(\frac{1}{2}\pi, q)}{\pi k B_2^{(2n+2)}} \int_0^\pi \sin u \cosh z \sinh(2k \cos u \sinh z) \text{se}_{2n+2}(u, q) du \quad (7) \\
 &= \frac{(-1)^n 2 \text{se}'_{2n+2}(0, q)}{\pi k B_2^{(2n+2)}} \int_0^\pi \cos u \sinh z \sinh(2k \sin u \cosh z) \text{se}_{2n+2}(u, q) du. \quad (8)
 \end{aligned}$$

The evaluations of (1)–(8) are given at (2), (3), (12), (13), (22), (23), (32), (33) § 8.30. All the representations of the modified Mathieu functions are first solutions of (1) § 2.31, provided  $a$  has its proper value.

**10.30. Bessel-circular function nuclei.** Hitherto our nuclei have been limited to circular and hyperbolic functions. But the wave equation admits of a plurality of solutions, and other nuclei may, therefore, be derived. Any solution expressed in *modified* elliptical coordinates, which satisfies conditions (a), (b), 2° § 10.10, may be used as a nucleus for the integral (1) § 10.10.†

We commence by transforming

$$\frac{\partial^2 \chi}{\partial x^2} + \frac{\partial^2 \chi}{\partial y^2} + k_1^2 \chi = 0, \quad (1)$$

to cylindrical polar coordinates, where  $x = r \cos \alpha$ ,  $y = r \sin \alpha$ . By established procedure we obtain

$$\frac{\partial^2 \chi}{\partial r^2} + \frac{1}{r} \frac{\partial \chi}{\partial r} + \frac{1}{r^2} \frac{\partial^2 \chi}{\partial \alpha^2} + k_1^2 \chi = 0. \quad (2)$$

Writing  $\chi = U(r)V(\alpha)$  and using analysis akin to that in § 9.21 yields the two ordinary equations

$$\frac{d^2 U}{dr^2} + \frac{1}{r} \frac{dU}{dr} + \left(k_1^2 - \frac{\nu^2}{r^2}\right) U = 0, \quad (3)$$

and

$$\frac{d^2 V}{d\alpha^2} + \nu^2 V = 0, \quad (4)$$

† Provided the integral converges.

$\nu^2$  being the separation constant. The formal solutions of (3), (4) are, respectively,  $J_\nu(k_1 r)$ ,  $Y_\nu(k_1 r)$ ; and  $\cos \nu\alpha$ ,  $\sin \nu\alpha$ . Thus if  $J_\nu(k_1 r)\cos \nu\alpha$ ,  $J_\nu(k_1 r)\sin \nu\alpha$ ,  $Y_\nu(k_1 r)\cos \nu\alpha$ ,  $Y_\nu(k_1 r)\sin \nu\alpha$  are expressed in *modified* elliptical coordinates, we get the sets of B.F. nuclei in Table 17. Each nucleus satisfies conditions (a), (b), 2° § 10.10 and the integral (1) § 10.10 converges if due regard is paid to the phase and modulus of  $z$ .

TABLE 17. *Bessel-circular function nuclei:  $k^2$  real  $> 0$*

	Nucleus $\chi(r, \alpha) = U(r)V(\alpha)$ ( $m = 0, 1, 2, \dots$ )	$\phi(u)$	$y(z)$	$y(iz)$	Remarks
1	$J_{2m}(k_1 r) \frac{\cos(2m\alpha)}{\sin(2m\alpha)}$	$\text{ce}_{2m}(u, q)$	$\text{ce}_{2m}(z, q)$	$\text{Ce}_{2m}(z, q)$	$r = h[\frac{1}{2}(\cos 2u + \cos 2z)]^{\frac{1}{2}}$ for $y(z)$ ; $\chi$ in 1, 2, are then periodic and symmetrical in $u, z$ : period $\pi, 2\pi$ , respectively. In (3), (4) replace $\cos 2z$ by $\cosh 2z$ , $R(z) > 0$ . $\chi$ in 3, 4, are non-periodic, as also are Fey, Gey (see § 8.11). The nuclei for $y(iz)$ are skew-symmetrical in $u, z$ .
2	$J_{2m+1}(k_1 r) \frac{\cos(2m+1)\alpha}{\sin(2m+1)\alpha}$	$\text{ce}_{2m+1}(u, q)$	$\text{ce}_{2m+1}(z, q)$	$\text{Ce}_{2m+1}(z, q)$	
3	$Y_{2m}(k_1 r) \frac{\cos(2m\alpha)}{\sin(2m\alpha)}$	$\text{ce}_{2m}(u, q)$	—	Fey <sub>2m</sub> ( $z, q$ ) Gey <sub>2m</sub> ( $z, q$ )	
4	$Y_{2m+1}(k_1 r) \frac{\cos(2m+1)\alpha}{\sin(2m+1)\alpha}$	$\text{ce}_{2m+1}(u, q)$	—	Fey <sub>2m+1</sub> ( $z, q$ ) Gey <sub>2m+1</sub> ( $z, q$ )	

Formula for  $r$ .  $r = (x^2 + y^2)^{\frac{1}{2}}$  with

$$x = h \cos u \cos z, \quad y = ih \sin u \sin z,$$

the modified elliptical coordinates. Thus

$$r = h[\frac{1}{2}(\cos 2u + \cos 2z)]^{\frac{1}{2}} \quad (5)$$

and, since  $k_1 h = 2k$ ,

$$k_1 r = k[2(\cos 2u + \cos 2z)]^{\frac{1}{2}}. \quad (6)$$

$Y_p$  has a singularity at the origin, and since  $k_1 r$  has zeros when  $\cos 2u = -\cos 2z$ , (6) cannot be used as the argument of the  $Y$  function if  $z$  is real. Writing  $iz$  for  $z$ ,  $R(z) > 0$ , there are no zeros ( $u$  real), so we obtain the argument for the  $J, Y$  functions used in the nuclei for the modified Mathieu functions in column 5, Table 17, i.e.

$$k_1 r = k[2(\cos 2u + \cosh 2z)]^{\frac{1}{2}}. \quad (7)$$

Formulae for  $\cos p\alpha$ ,  $\sin p\alpha$ . From above,

$$\cos \alpha = x/r = \cos u \cos z / [\frac{1}{2}(\cos 2u + \cos 2z)]^{\frac{1}{2}} \quad (8)$$

$$\text{and} \quad \sin \alpha = y/r = i \sin u \sin z / [\frac{1}{2}(\cos 2u + \cos 2z)]^{\frac{1}{2}}. \quad (9)$$

Then by de Moivre's theorem

$$(\cos p\alpha + i \sin p\alpha) = (\cos \alpha + i \sin \alpha)^p, \quad (10)$$

so  $\cos p\alpha$ ,  $\sin p\alpha$  are obtained by equating real and imaginary parts in (10), and substituting from (8), (9). The remarks in column 6, Table 17, may now be confirmed.

**10.31. Hankel-circular function nuclei:  $k^2$  real  $> 0$ .** By (4) § 8.14

$$\text{Fek}_{2n}(z, q) = \frac{1}{2}[i \text{Ce}_{2n}(z, q) - \text{Fey}_{2n}(z, q)] \quad (a_{2n}), \quad (1)$$

so by Table 17, § 10.30 we see that the nucleus for  $\text{Fek}_{2n}(z, q)$  is

$$\frac{1}{2}[iJ_{2m}(k_1 r) - Y_{2m}(k_1 r)]\cos 2m\alpha = \frac{1}{2}iH_{2m}^{(1)}(k_1 r)\cos 2m\alpha, \quad (2)$$

in which  $k_1 r$  is given by (7) § 10.30, with  $R(z) > 0$ . Other nuclei are set out in Table 18.

TABLE 18. *Hankel-circular function nuclei:  $k^2$  real  $> 0$*

	Nucleus $\chi(r, \alpha)$ ( $m = 0, 1, 2, \dots$ )	$\phi(u)$ in (1) § 10.10	$y(z)$ in (1) § 10.10
1	$H_{2m}^{(1)}(k_1 r) \frac{\cos(2m\alpha)}{\sin(2m\alpha)}$	$\text{ce}_{2n}(u, q)$	$\text{Fek}_{2n}(z, q)$
2	$H_{2m+1}^{(1)}(k_1 r) \frac{\cos(2m+1)\alpha}{\sin(2m+1)\alpha}$	$\text{ce}_{2n+1}(u, q)$	$\text{Fek}_{2n+1}(z, q)$

The Hankel function may be expressed in terms of the *K*-Bessel function by the relationship (1) § 8.14.

**10.32. Nuclei for  $k^2$  real  $< 0$ .** Here we write  $-k_1^2$  for  $k_1^2$  in (3) § 10.30: (4) § 10.30 is unchanged. The formal solutions of (3) § 10.30 are now the modified B.F.  $I_\nu(k_1 r)$  and  $K_\nu(k_1 r)$ . Hence we have the nuclei  $I_\nu(k_1 r)\cos \nu\alpha$ ,  $I_\nu(k_1 r)\sin \nu\alpha$ ,  $K_\nu(k_1 r)\cos \nu\alpha$ , and  $K_\nu(k_1 r)\sin \nu\alpha$ .  $Y_\nu(ik_1 r)$  is also a solution of (3) § 10.30, so  $Y_\nu(ik_1 r)\cos \nu\alpha$  and  $Y_\nu(ik_1 r)\sin \nu\alpha$  may be used as alternative nuclei. The nuclei are set out in Table 19.

TABLE 19. *Bessel-circular function nuclei:  $k^2$  real  $< 0$*

	Nucleus $\chi(r, \alpha)$ ( $m = 0, 1, 2, \dots$ )	$\phi(u)$	$y(z)$	$y(iz)$	Remarks
1	$I_{2m}(k_1 r) \frac{\cos(2m\alpha)}{\sin(2m\alpha)}$	$\text{ce}_{2n}(u, -q)$	$\text{ce}_{2n}(z, -q)$	$\text{Ce}_{2n}(z, -q)$	Those in Table 17 apply here, <i>mutatis mutandis</i> . If $Y(ik_1 r)$ is used in (3), (4), Fey, Gey are obtained for $y(iz)$ .
2	$I_{2m+1}(k_1 r) \frac{\cos(2m+1)\alpha}{\sin(2m+1)\alpha}$	$\text{ce}_{2n+1}(u, -q)$	$\text{ce}_{2n+1}(z, -q)$	$\text{Ce}_{2n+1}(z, -q)$	
3	$K_{2m}(k_1 r) \frac{\cos(2m\alpha)}{\sin(2m\alpha)}$	$\text{ce}_{2n}(u, -q)$	—	$\text{Fek}_{2n}(z, -q)$	
4	$K_{2m+1}(k_1 r) \frac{\cos(2m+1)\alpha}{\sin(2m+1)\alpha}$	$\text{ce}_{2n+1}(u, -q)$	—	$\text{Fek}_{2n+1}(z, -q)$	

**10.33. Integral equation for  $\text{ce}_{2n}(z, q)$  with Bessel nucleus.** In 1, Table 17 put  $m = 0$ ,  $\phi(u) = \text{ce}_{2n}(u, q)$ , and insert  $\chi, \phi$  in (8) § 10.10 with upper limit  $\pi$ . Then

$$\text{ce}_{2n}(z, q) = \varphi_{2n} \int_0^\pi J_0\{k[2(\cos 2u + \cos 2z)]^{\frac{1}{2}}\} \text{ce}_{2n}(u, q) du. \quad (1)$$

To determine  $\varphi_{2n}$ , let  $z = 0$ , then from (1)

$$\text{ce}_{2n}(0, q) = \varphi_{2n} \int_0^\pi J_0(2k \cos u) \sum_{r=0}^\infty A_{2r}^{(2n)} \cos 2ru du. \quad (2)$$

Now by (2) § 10.34, with  $z = 0$ ,

$$\begin{aligned} & \int_0^\pi J_0(2k \cos u) \cos 2ru du \\ &= \int_0^\pi \left[ J_0^2(k) + 2 \sum_{m=1}^\infty (-1)^m J_m^2(k) \cos 2mu \right] \cos 2ru du \end{aligned} \quad (3)$$

$$= (-1)^r \pi J_r^2(k). \quad (4)$$

Hence from (2), (4) we obtain

$$\varphi_{2n} = \text{ce}_{2n}(0, q) / \pi \sum_{r=0}^\infty (-1)^r A_{2r}^{(2n)} J_r^2(k). \quad (5)$$

An alternative expression for  $\varphi_{2n}$  may be derived as follows: Insert the value of  $\lambda_{2n}$  from (5) § 10.12 into (4) § 10.12 and integrate both sides of the latter with respect to  $z$  from 0 to  $\pi$ . Then

$$\begin{aligned} & \int_0^\pi \sum_{r=0}^\infty A_{2r}^{(2n)} \cos 2rz dz = \pi A_0^{(2n)} \\ &= \frac{\text{ce}_{2n}(\frac{1}{2}\pi, q)}{A_0^{(2n)}} \int_0^\pi \sum_{r=0}^\infty (-1)^r A_{2r}^{(2n)} J_{2r}(2k \cos z) dz \end{aligned} \quad (6)$$

$$= \frac{\text{ce}_{2n}(\frac{1}{2}\pi, q)}{A_0^{(2n)}} \left[ \pi \sum_{r=0}^\infty (-1)^r A_{2r}^{(2n)} J_r^2(k) \right], \quad (7)$$

since  $\int_0^\pi J_{2r}(2k \cos z) dz = \pi J_r^2(k)$ . Thus from (7) we get

$$\sum_{r=0}^\infty (-1)^r A_{2r}^{(2n)} J_r^2(k) = [A_0^{(2n)}]^2 / \text{ce}_{2n}(\frac{1}{2}\pi, q). \quad (8)$$

Substituting the r.h.s. of (8) in the denominator of (5) leads to

$$\varphi_{2n} = \text{ce}_{2n}(0, q) \text{ce}_{2n}(\frac{1}{2}\pi, q) / \pi [A_0^{(2n)}]^2. \quad (9)$$

**10.34. Expansions of Mathieu functions in Bessel function products.** We apply the addition theorem

$$J_0[(v_1'^2 + v_2'^2 + 2v_1'v_2'\cos 2u)^{\frac{1}{2}}] = \sum_{m=0}^{\infty} (-1)^m \epsilon_m J_m(v_1') J_m(v_2') \cos 2mu, \quad (1)$$

where  $\epsilon_0 = 1$ ,  $\epsilon_m = 2$  for  $m \geq 1$ . Let  $v_1' = ke^{iz}$ ,  $v_2' = ke^{-iz}$ , and (1) gives

$$J_0\{k[2(\cos 2u + \cos 2z)]^{\frac{1}{2}}\} = \sum_{m=0}^{\infty} (-1)^m \epsilon_m J_m(ke^{-iz}) J_m(ke^{iz}) \cos 2mu. \quad (2)$$

Substituting from (2) into (1) § 10.33 we obtain

$$\begin{aligned} & \text{ce}_{2n}(z, q) \\ &= \varphi_{2n} \sum_{r=0}^{\infty} \sum_{m=0}^{\infty} (-1)^m A_{2r}^{(2n)} \epsilon_m J_m(ke^{-iz}) J_m(ke^{iz}) \int_0^{\pi} \cos 2ru \cos 2mu \, du, \end{aligned} \quad (3)$$

term-by-term integration being permissible, since the series before and after integration are absolutely and uniformly convergent. Now

$$\int_0^{\pi} \cos 2ru \cos 2mu \, du = \begin{cases} \pi & (m = r = 0), \\ 0 & (m \neq r > 0), \\ \frac{1}{2}\pi & (m = r > 0). \end{cases} \quad (4)$$

Hence (3) becomes

$$\text{ce}_{2n}(z, q) = \varphi_{2n} \pi \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} J_r(ke^{-iz}) J_r(ke^{iz}), \quad (5)$$

so this series satisfies  $y'' + (a - 2k^2 \cos 2z)y = 0$ ,  $k^2 > 0$ . When  $z = 0$ , (5) gives

$$\varphi_{2n} = \text{ce}_{2n}(0, q) / \pi \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} J_r^2(k), \quad (6)$$

as at (5) § 10.33.

If in (5) we write  $iz$  for  $z$ , this being permissible by § 13.60, then

$$\text{Ce}_{2n}(z, q) = \varphi_{2n} \pi \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} J_r(ke^{-z}) J_r(ke^z), \quad (7)$$

so the r.h.s. satisfies  $y'' - (a - 2k^2 \cosh 2z)y = 0$ ,  $k^2 > 0$ .

Substituting  $(\frac{1}{2}\pi - z)$  for  $z$  in (5) leads to

$$\text{ce}_{2n}(z, -q) = (-1)^n \varphi_{2n} \pi \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} I_r(ke^{-iz}) I_r(ke^{iz}), \quad (8)$$

so the r.h.s. satisfies  $y'' + (a + 2k^2 \cos 2z)y = 0$ ,  $k^2 > 0$ .

Putting  $iz$  for  $z$  in (8), or  $(\frac{1}{2}\pi i + z)$  for  $z$  in (7), yields

$$\text{Ce}_{2n}(z, -q) = (-1)^n \varphi_{2n} \pi \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} I_r(ke^{-z}) I_r(ke^z), \quad (9)$$

so the r.h.s. satisfies  $y'' - (a + 2k^2 \cosh 2z)y = 0$ ,  $k^2 > 0$ . The multiplier  $(-1)^n$  is used in accordance with the definitions in §§ 2.18, 2.31.

### 10.35. Integral relation for $\text{Se}_{2n+1}(z, q)$ with Bessel nucleus.

In (2) Table 17, if we put  $m = 0$ ,  $iz$  for  $z$ , take  $\phi(u) = \text{se}_{2n+1}(u, q)$ , (8) § 10.10 gives, with the aid of (4) § 2.30,

$$\text{Se}_{2n+1}(z, q) = \varphi_{2n+1} \int_0^{2\pi} J_1(k_1 r) \sin \alpha \sum_{s=0}^{\infty} B_{2s+1}^{(2n+1)} \sin(2s+1)u \, du, \quad (1)$$

where  $k_1 r = k[2(\cos 2u + \cosh 2z)]^{\frac{1}{2}} = k(e^{2z} + e^{-2z} + 2 \cos 2u)^{\frac{1}{2}}$ . Now if  $\mathfrak{C}$  is a cylinder function, then [214, (4), p. 365]

$$\frac{\mathfrak{C}_\nu(\varpi)}{\varpi^\nu} = 2^\nu \Gamma(\nu) \sum_{m=0}^{\infty} (-1)^m (m+\nu) \frac{J_{m+\nu}(v_1) \mathfrak{C}_{m+\nu}(v_2) C_m^\nu(\cos 2u)}{v_1^\nu v_2^\nu}, \quad (2)$$

with  $\varpi^2 = v_1^2 + v_2^2 + 2v_1 v_2 \cos 2u$ ,  $|v_1| < |v_2|$ , while  $C_m^\nu(\cos 2u)$  is the coefficient of  $\alpha_1^m$  in the expansion of  $(1 - 2\alpha_1 \cos 2u + \alpha_1^2)^{-\nu}$  in ascending powers of  $\alpha_1$ . Thus

$$C_m^\nu(\cos 2u) = \sum_{s=0}^{\leq \frac{1}{2}m} (-1)^s \frac{2^{m-2s} \Gamma(\nu+m-s) \cos^{m-2s} 2u}{(m-2s)! s! \Gamma(\nu)} \quad (3)$$

and in particular

$$\sin u \, C_m^1(\cos 2u) = \sin(2m+2)u/2 \cos u = (-1)^m \sum_{p=0}^m (-1)^p \sin(2p+1)u, \quad (4)$$

the third member being obtained by expressing the second in exponentials and expanding. Also from (5), (9) § 10.30 with  $-iz$  for  $z$

$$\sin \alpha = y/r = h \sinh z \sin u/r = 2k \sinh z \sin u/k_1 r. \quad (5)$$

Writing  $J$  for  $\mathfrak{C}$ ,  $v_1 = ke^{-z}$ ,  $v_2 = ke^z$ ,  $\nu = 1$  in (2), and using (4), (5), we obtain

$$J_1(k_1 r) \sin \alpha = \frac{4}{k} \sinh z \sum_{m=0}^{\infty} (m+1) w_{m+1} \sum_{p=0}^m (-1)^p \sin(2p+1)u, \quad (6)$$

with

$$w_{m+1} = J_{m+1}(v_1) J_{m+1}(v_2).$$

Hence from (1), (6)

$$\begin{aligned} \text{Se}_{2n+1}(z, q) &= \varphi_{2n+1} \frac{4}{k} \sinh z \sum_{m=0}^{\infty} w_{m+1} (m+1) \times \\ &\times \int_0^{2\pi} \sum_{p=0}^m (-1)^p \sin(2p+1)u \sum_{s=0}^{\infty} B_{2s+1}^{(2n+1)} \sin(2s+1)u \, du. \quad (7) \end{aligned}$$

Since  $\int_0^{2\pi} \sin(2m+1)u \sin(2s+1)u \, du = \begin{cases} 0 & (m \neq s) \\ \pi & (m = s \geq 0) \end{cases}$ , the value of  $(m+1)$  times the integral in (7) is found to be

$$\pi \bar{B}_{2m+1} = \pi(m+1)[B_1 - B_3 + B_5 - \dots + (-1)^m B_{2m+1}]. \quad (8)$$

Hence by (7), (8)

$$\text{Se}_{2n+1}(z, q) = \varphi_{2n+1} \frac{4\pi \sinh z}{k} \sum_{m=0}^{\infty} \bar{B}_{2m+1} w_{m+1}. \quad (9)$$

**10.36. Alternative form of (9) § 10.35.** By applying the formula

$$J_\nu(v) = \frac{2(\nu+1)}{v} J_{\nu+1}(v) - J_{\nu+2}(v), \quad (1)$$

to

$$W_\nu = J_\nu(v_1)J_{\nu+1}(v_2) - J_{\nu+1}(v_1)J_\nu(v_2), \quad (2)$$

and writing  $w_{\nu+1} = J_{\nu+1}(v_1)J_{\nu+1}(v_2)$ , we obtain the recurrence relation

$$W_\nu = \frac{4}{k}(\nu+1)\sinh z \cdot w_{\nu+1} + W_{\nu+1}. \quad (3)$$

Applying (3) to its r.h.s. repeatedly and writing  $m$  for  $\nu$  yields

$$W_m = \frac{4}{k} \sinh z [(m+1)w_{m+1} + (m+2)w_{m+2} + (m+3)w_{m+3} + \dots]. \quad (4)$$

Accordingly we have

$$\begin{aligned} \sum_{m=0}^{\infty} (-1)^m B_{2m+1}^{(2n+1)} W_m \\ = \frac{4}{k} \sinh z [B_1(w_1 + 2w_2 + 3w_3 + \dots) - \\ - B_3(2w_2 + 3w_3 + \dots) + B_5(3w_3 + 4w_4 + \dots) - \dots] \end{aligned} \quad (5)$$

$$= \frac{4}{k} \sinh z \sum_{m=0}^{\infty} (m+1)[B_1 - B_3 + B_5 - \dots + (-1)^m B_{2m+1}] w_{m+1} \quad (6)$$

$$= \frac{4}{k} \sinh z \sum_{m=0}^{\infty} \bar{B}_{2m+1} w_{m+1}. \quad (7)$$

Hence from (9) § 10.35 and (7) above, we obtain

$$\text{Se}_{2n+1}(z, q) = \varphi_{2n+1} \pi \sum_{r=0}^{\infty} (-1)^r B_{2r+1}^{(2n+1)} [J_r(v_1)J_{r+1}(v_2) - J_{r+1}(v_1)J_r(v_2)]. \quad (8)$$

**10.37. Determination of  $\varphi_{2n+1}$ .** When  $z \rightarrow +\infty$ , the asymptotic form of  $\text{Se}_{2n+1}(z, q)$  is, by (8) § 10.36,

$$\text{Se}_{2n+1}(z, q) \sim -\varphi_{2n+1} \pi B_1(2/\pi v_2)^{\frac{1}{2}} \cos(v_2 + \frac{1}{4}\pi). \quad (1)$$

Comparing this with (5) § 11.10, we see that

$$\varphi_{2n+1} = s_{2n+1}/\pi B_1. \quad (2)$$

With this value of  $\varphi_{2n+1}$  in (8) § 10.36, (5) § 13.11 is reproduced.

**10.38. Integral relations for  $\text{Fey}_{2n}(z, q)$ ,  $\text{Gey}_{2n+1}(z, q)$ .** From Table 17 we get

$$\text{Fey}_{2n}(z, q) = \bar{\varphi}_{2n} \int_0^{2\pi} Y_0\{k[2(\cos 2u + \cosh 2z)]^{\frac{1}{2}}\} \text{ce}_{2n}(u, q) du. \quad (1)$$

By § 10.34 and (2) § 10.35 we see that the value of the integral may be obtained from the r.h.s. of (7) § 10.34, if  $Y_r(ke^z)$  be written for  $J_r(ke^z)$ . Thus

$$\text{Fey}_{2n}(z, q) = \bar{\varphi}_{2n} 2\pi \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} J_r(ke^{-z}) Y_r(ke^z). \quad (2)$$

If we let  $z \rightarrow +\infty$  and equate the asymptotic form of the r.h.s. to (9) § 11.10, we find that

$$\bar{\varphi}_{2n} = \text{ce}_{2n}(0, q) \text{ce}_{2n}(\frac{1}{2}\pi, q)/2\pi A_0^2. \quad (3)$$

With this value of  $\bar{\varphi}_{2n}$ , (2) gives the B.F. product series for  $\text{Fey}_{2n}(z, q)$  at (1) § 13.20.

Again, from Table 17 we get

$$\text{Gey}_{2n+1}(z, q) = \bar{\varphi}_{2n+1} \int_0^{2\pi} Y_1\{k[2(\cos 2u + \cosh 2z)]^{\frac{1}{2}}\} \sin \alpha \text{se}_{2n+1}(u, q) du; \quad (4)$$

and from (2) § 10.35 we see that the analysis for the present case is the same as that in §§ 10.35, 10.36, provided  $Y_m(ke^z)$  be written for  $J_m(ke^z)$ . Then by (8) § 10.36

$$\text{Gey}_{2n+1}(z, q) = \bar{\varphi}_{2n+1} \pi \sum_{r=0}^{\infty} (-1)^r B_{2r+1}^{(2n+1)} [J_r(v_1) Y_{r+1}(v_2) - J_{r+1}(v_1) Y_r(v_2)]. \quad (5)$$

If we determine  $\bar{\varphi}_{2n+1}$  as indicated above, the expansion (8) § 13.20 is reproduced. Moreover, we have here a method of obtaining the B.F. product series representations of the modified Mathieu functions of the first and second kinds, which is an alternative to that given in Chapter XIII.

**10.40. Integral relations for  $Fek_m$ ,  $Ce_m$ ,  $Fey_m$ ,  $Gek_m$ ,  $Se_m$ ,  $Gey_m$ ,  $q > 0$ , with infinite upper limit.** We commence with the formula

$$K_{2r}(z) = \int_0^{\infty} e^{-z \cosh u} \cosh 2ru \, du. \quad (1)$$

This integral converges uniformly with respect to  $z$  if  $R(z) \geq x$ ,  $x > 0$ . Under this condition, if  $-2ik \cosh z$  be written for  $z$ , we get

$$\sum_{r=0}^{\infty} A_{2r}^{(2n)} K_{2r}(-2ik \cosh z) = \int_0^{\infty} \sum_{r=0}^{\infty} e^{2ik \cosh z \cosh u} A_{2r}^{(2n)} \cosh 2ru \, du \quad (2)$$

$$= \int_0^{\infty} e^{2ik \cosh z \cosh u} Ce_{2n}(u, q) \, du. \quad (3)$$

If  $z$  and  $k$  are real, the above restriction may be removed, since the real and imaginary parts of (3) are absolutely and uniformly convergent by § 10.42. Then by (5) § 8.14 and (3) above we have the integral relationship

$$Fek_{2n}(z, q) = \frac{ce_{2n}(\frac{1}{2}\pi, q)}{\pi A_0^{(2n)}} \int_0^{\infty} e^{2ik \cosh z \cosh u} Ce_{2n}(u, q) \, du. \quad (4)$$

Applying (4) § 8.14 to (4), on equating real and imaginary parts, we obtain

$$Ce_{2n}(z, q) = \frac{2 ce_{2n}(\frac{1}{2}\pi, q)}{\pi A_0^{(2n)}} \int_0^{\infty} \sin(2k \cosh z \cosh u) Ce_{2n}(u, q) \, du \quad (5)$$

and

$$Fey_{2n}(z, q) = -\frac{2 ce_{2n}(\frac{1}{2}\pi, q)}{\pi A_0^{(2n)}} \int_0^{\infty} \cos(2k \cosh z \cosh u) Ce_{2n}(u, q) \, du. \quad (6)$$

Similar analysis leads to the following:

$$Fek_{2n+1}(z, q) = -\frac{ce'_{2n+1}(\frac{1}{2}\pi, q)}{k\pi A_1^{(2n+1)}} \int_0^{\infty} e^{2ik \cosh z \cosh u} Ce_{2n+1}(u, q) \, du, \quad (7)$$

$$Ce_{2n+1}(z, q) = \frac{2 ce'_{2n+1}(\frac{1}{2}\pi, q)}{k\pi A_1^{(2n+1)}} \int_0^{\infty} \cos(2k \cosh z \cosh u) Ce_{2n+1}(u, q) \, du, \quad (8)$$

and

$$Fey_{2n+1}(z, q) = \frac{2 ce'_{2n+1}(\frac{1}{2}\pi, q)}{k\pi A_1^{(2n+1)}} \int_0^{\infty} \sin(2k \cosh z \cosh u) Ce_{2n+1}(u, q) \, du. \quad (9)$$

To derive integral relations for  $\text{Gek}_m$ ,  $\text{Se}_m$ ,  $\text{Gey}_m$  we commence with the integral relationship [132]

$$\nu K_\nu(z) = z \int_0^\infty e^{-z \cosh u} \sinh u \sinh \nu u \, du = \frac{1}{2} \pi \nu e^{\frac{1}{2}(\nu+1)i} H_\nu^{(1)}(zi), \quad (10)$$

$R(z) > 0$ . Then by aid of formulae in § 8.14 we find that

$$\begin{aligned} & \text{Gek}_{2n+1}(z, q) \\ &= -\frac{2i \text{se}_{2n+1}(\frac{1}{2}\pi, q)}{\pi B_1^{(2n+1)}} \int_0^\infty e^{2ik \cosh z \cosh u} \sinh z \sinh u \text{Se}_{2n+1}(u, q) \, du, \end{aligned} \quad (11)$$

$$\begin{aligned} & \text{Se}_{2n+1}(z, q) \\ &= -\frac{4 \text{se}_{2n+1}(\frac{1}{2}\pi, q)}{\pi B_1^{(2n+1)}} \int_0^\infty \sin(2k \cosh z \cosh u) \sinh z \sinh u \text{Se}_{2n+1}(u, q) \, du, \end{aligned} \quad (12)$$

$$\begin{aligned} & \text{Gey}_{2n+1}(z, q) \\ &= \frac{4 \text{se}_{2n+1}(\frac{1}{2}\pi, q)}{\pi B_1^{(2n+1)}} \int_0^\infty \cos(2k \cosh z \cosh u) \sinh z \sinh u \text{Se}_{2n+1}(u, q) \, du, \end{aligned} \quad (13)$$

$$\begin{aligned} & \text{Gek}_{2n+2}(z, q) \\ &= -\frac{2i \text{se}'_{2n+2}(\frac{1}{2}\pi, q)}{k\pi B_2^{(2n+2)}} \int_0^\infty e^{2ik \cosh z \cosh u} \sinh z \sinh u \text{Se}_{2n+2}(u, q) \, du, \end{aligned} \quad (14)$$

$$\begin{aligned} & \text{Se}_{2n+2}(z, q) \\ &= -\frac{4 \text{se}'_{2n+2}(\frac{1}{2}\pi, q)}{k\pi B_2^{(2n+2)}} \int_0^\infty \cos(2k \cosh z \cosh u) \sinh z \sinh u \text{Se}_{2n+2}(u, q) \, du, \end{aligned} \quad (15)$$

$$\begin{aligned} & \text{Gey}_{2n+2}(z, q) \\ &= -\frac{4 \text{se}'_{2n+2}(\frac{1}{2}\pi, q)}{k\pi B_2^{(2n+2)}} \int_0^\infty \sin(2k \cosh z \cosh u) \sinh z \sinh u \text{Se}_{2n+2}(u, q) \, du. \end{aligned} \quad (16)$$

Relations (11)–(16) may also be expressed as follows:

$$\begin{aligned} & \text{Gek}_{2n+1}(z, q) \\ &= \frac{\text{se}_{2n+1}(\frac{1}{2}\pi, q)}{k\pi B_1^{(2n+1)}} \tanh z \int_0^\infty e^{2ik \cosh z \cosh u} \text{Se}'_{2n+1}(u, q) \, du, \end{aligned} \quad (17)$$

$$\begin{aligned} & \text{Se}_{2n+1}(z, q) \\ &= -\frac{2 \text{se}_{2n+1}(\frac{1}{2}\pi, q)}{k\pi B_1^{(2n+1)}} \tanh z \int_0^\infty \cos(2k \cosh z \cosh u) \text{Se}'_{2n+1}(u, q) \, du, \end{aligned} \quad (18)$$

$\text{Gey}_{2n+1}(z, q)$

$$= -\frac{2 \text{se}_{2n+1}(\frac{1}{2}\pi, q)}{k\pi B_1^{(2n+1)}} \tanh z \int_0^\infty \sin(2k \cosh z \cosh u) \text{Se}'_{2n+1}(u, q) du, \quad (19)$$

$\text{Gek}_{2n+2}(z, q)$

$$= \frac{\text{se}'_{2n+2}(\frac{1}{2}\pi, q)}{k^2\pi B_2^{(2n+2)}} \tanh z \int_0^\infty e^{2ik \cosh z \cosh u} \text{Se}'_{2n+2}(u, q) du, \quad (20)$$

$\text{Se}_{2n+2}(z, q)$

$$= \frac{2 \text{se}'_{2n+2}(\frac{1}{2}\pi, q)}{k^2\pi B_2^{(2n+2)}} \tanh z \int_0^\infty \sin(2k \cosh z \cosh u) \text{Se}'_{2n+2}(u, q) du, \quad (21)$$

$\text{Gey}_{2n+2}(z, q)$

$$= -\frac{2 \text{se}'_{2n+2}(\frac{1}{2}\pi, q)}{k^2\pi B_2^{(2n+2)}} \tanh z \int_0^\infty \cos(2k \cosh z \cosh u) \text{Se}'_{2n+2}(u, q) du. \quad (22)$$

On integrating by parts and using the result that

$$\text{Se}_m(0) = \text{Se}_m(\infty) = 0,$$

(17)–(22) reduce to (11)–(16), respectively.

(4), (7), (11), (14), (17), (20) converge if  $k \cosh z$  is complex, provided that its imaginary part is greater than zero. The arguments of the circular functions in the integrals obtained by separation into real and imaginary parts must be real. The nuclei in the integral equations (5), (8), (12), (15) are symmetrical in  $u$  and  $z$ . §§ 10.42–10.45 are based on  $k > 0, z$  real:  $z \geq 0$  in (4)–(9),  $z > 0$  in (11)–(22).

**10.41. Integral relations for  $\text{Fek}_m(z, -q)$ ,  $\text{Gek}_m(z, -q)$ .** These are obtained by applying (7), etc., § 8.40 to (4), (7), (11), (14) § 10.40. For example, if  $R(z) > 0$ ,

$$\text{Fek}_{2n}(z, -q) = \frac{(-1)^n \text{ce}_{2n}(\frac{1}{2}\pi, q)}{\pi A_0^{(2n)}} \int_0^\infty e^{-2k \sinh z \cosh u} \text{Ce}_{2n}(u, q) du. \quad (1)$$

The remaining relations may be obtained by the reader. There are, however, alternative relations for these functions, which we shall now give. Applying (1) § 10.40 to (9), (19) § 8.30, we obtain

$$\text{Fek}_{2n}(z, -q) = \frac{\text{ce}_{2n}(0, q)}{\pi A_0^{(2n)}} \int_0^\infty e^{-2k \cosh z \cosh u} \text{Ce}_{2n}(u, -q) du. \quad (2)$$

It should be noticed that for  $Ce_{2n}$ ,  $q > 0$  in (1) and  $< 0$  in (2).

$$Fek_{2n+1}(z, -q) = \frac{se'_{2n+1}(0, q)}{k\pi B_1^{(2n+1)}} \int_0^\infty e^{-2k \cosh z \cosh u} Ce_{2n+1}(u, -q) du. \quad (3)$$

Similarly from (10) § 10.40 and (29), (39) § 8.30 we find that if  $z > 0$

$$\begin{aligned} &Gek_{2n+1}(z, -q) \\ &= \frac{2ce_{2n+1}(0, q)}{\pi A_1^{(2n+1)}} \int_0^\infty e^{-2k \cosh z \cosh u} \sinh z \sinh u Se_{2n+1}(u, -q) du, \quad (4) \end{aligned}$$

$$\begin{aligned} &Gek_{2n+2}(z, -q) \\ &= \frac{2se'_{2n+2}(0, q)}{k\pi B_2^{(2n+2)}} \int_0^\infty e^{-2k \cosh z \cosh u} \sinh z \sinh u Se_{2n+2}(u, -q) du. \quad (5) \end{aligned}$$

If  $(\frac{1}{2}\pi i + z)$  be written for  $z$  in the integrals in § 10.40 corresponding to  $Ce_m$ ,  $Fey_m$ ,  $Se_m$ ,  $Gey_m$ , they diverge.

**10.42. Convergence of integrals (4)–(9) § 10.40.** In that section functions are defined by infinite integrals whose properties we shall now investigate. Constant multipliers will be omitted for brevity. We exemplify using (6) § 10.40. Both members of the integrand are continuous in  $0 \leq u \leq u_0$ , however large  $u_0$  may be, the continuity of the first member holding in any closed interval of  $z$  real. Thus  $\int_0^{u_0}$  exists, so we consider  $\int_{u_0}^\infty$  with  $u_0$  extremely large. Then by (2) § 11.10 the asymptotic form of  $Ce_{2n}(u) \propto x^{-\frac{1}{2}} \sin(x + \frac{1}{4}\pi)$ , where  $x = 2k \cosh u$ ,  $du \simeq dx/x$ . With these substitutions the integral for consideration is

$$I = \int_{x_0}^\infty \cos(x \cosh z) \sin(x + \frac{1}{4}\pi) x^{-\frac{1}{2}} dx. \quad (1)$$

Since  $|\cos(x \cosh z) \sin(x + \frac{1}{4}\pi)| \leq 1$  if  $z$  is real, we get

$$I \leq \int_{x_0}^\infty x^{-\frac{1}{2}} dx = 2x_0^{-\frac{1}{2}}, \quad (2)$$

so the original integral converges absolutely. Further, the convergence is independent of  $z$  in any closed interval  $0 \leq z \leq z_2$ , so (6) § 10.40 is absolutely and uniformly convergent therein. Consequently it represents a continuous function in the interval. In § 13.60

it is demonstrated that the series for  $\text{Fey}_{2n}(z, q)$ —the function represented by (6) § 10.40—is uniformly convergent in  $z_1 \leq z \leq z_2$ , and so represents a continuous function therein. The convergence of (4), (7) § 10.40 follows from that of their real and imaginary parts.

**10.43. Differentiation under the integral sign.** This is valid provided the resulting integral is uniformly convergent. To exemplify, we differentiate (6) § 10.40 with respect to  $z$ , and obtain (omitting the external multiplier)

$$\sinh z \int_0^\infty 2k \cosh u \sin(2k \cosh z \cosh u) \text{Ce}_{2n}(u, q) du. \quad (1)$$

Thus we consider the integral

$$\begin{aligned} I &= \sinh z \int_{x_0}^\infty \sin(x \cosh z) \sin(x + \tfrac{1}{4}\pi) x^{-\frac{1}{2}} dx \\ &= \tfrac{1}{2} \sinh z \int_{l \rightarrow +\infty}^l \{ -\cos[x(\cosh z + 1) + \tfrac{1}{4}\pi] + \\ &\quad + \cos[x(\cosh z - 1) - \tfrac{1}{4}\pi] \} x^{-\frac{1}{2}} dx. \end{aligned} \quad (2)$$

Now  $-\cos[ \quad ]$  oscillates between finite limits for any  $z$  in  $z_1 \leq z \leq z_2$  as  $l \rightarrow +\infty$ , while  $x^{-\frac{1}{2}} \rightarrow 0$  monotonically. Hence by a known theorem† the integral converges uniformly with respect to  $z$  in the interval. It vanishes at  $z = 0$ , owing to the factor  $\sinh z$ .

In the second integral of (3) write

$$x(\cosh z - 1) = y, \quad dx = dy/(\cosh z - 1),$$

and we get

$$I_2 = \frac{\tfrac{1}{2} \sinh z}{(\cosh z - 1)^{\frac{1}{2}}} \int_{y_0}^y \cos(y - \tfrac{1}{4}\pi) y^{-\frac{1}{2}} dy, \quad (4)$$

the upper limit being  $y = x(\cosh z - 1)$ ,  $x \rightarrow +\infty$ , and the lower limit  $y_0 = x_0(\cosh z - 1)$ .

From what precedes it is clear that, excluding the region of  $z = 0$ , (4) is uniformly convergent in any closed interval  $z_1 \leq z \leq z_2$ . When  $z \rightarrow 0$ , the external factor tends to  $1/\sqrt{2}$ , the upper limit  $y \rightarrow \frac{1}{2}xz^2$ , and  $y_0 \rightarrow \frac{1}{2}x_0z^2$ . Thus as  $z \rightarrow 0$ ,  $y_0 \rightarrow 0$ , but  $y \rightarrow 0$  or  $\infty$  according to the way  $z \rightarrow 0$ , i.e. it is not *unique*. Hence (1) is uniformly convergent in  $0 < z_1 \leq z \leq z_2$ . Accordingly  $\text{Fey}'_{2n}(z, q)$ , as defined

† See Bromwich, *Theory of Infinite Series*.

by the integral, is continuous in  $z > 0$ . A second differentiation under the integral sign is not permissible, since the resulting integral is oscillatory and diverges owing to presence of the factor  $x^{\frac{1}{2}}$  in the integrand. The preceding conclusions apply equally to (5), (8), (9) § 10.40.

**10.44. Convergence of integrals (11)–(16) § 10.40.** The investigation follows on the lines of that in the preceding section. In all cases we get an integral akin to (3) § 10.43, so the integrals are uniformly convergent in  $z_1 \leq z \leq z_2$ . Thus they represent continuous functions. These integrals cannot be differentiated under the sign, since the resulting integrals diverge. As in § 10.43,  $z_1$  real  $> 0$ .

**10.45. Convergence of integrals in § 10.41.** The analytical procedure is similar to that in §§ 10.42, 10.43. Thus for (2) § 10.41 we consider

$$\int_{x_0}^{\infty} e^{-x \cosh z} (x^{-\frac{1}{2}} e^x) dx/x = \int_{x_0}^{\infty} e^{-x(\cosh z - 1)} x^{-\frac{1}{2}} dx \quad (1)$$

with  $x = 2k \cosh u$ . It is obvious that (1) is absolutely and uniformly convergent in  $0 \leq z \leq z_2$ , so  $\text{Fek}_{2n}(z, -q)$ , as defined by (2) § 10.41, is a continuous function of  $z$ . Differentiating (2) § 10.41 under the integral sign with respect to  $z$  leads to a consideration of

$$\int_{x_0}^{\infty} e^{-x(\cosh z - 1)} x^{-\frac{1}{2}} dx. \quad (2)$$

This is seen to be absolutely and uniformly convergent in  $z_1 \leq z \leq z_2$ , so long as the neighbourhood of  $z = 0$  is excluded. It diverges if  $z = 0$ . These conclusions apply equally to (3) § 10.41. In the case of (4), (5) § 10.41, integrals of type (2) above are involved, so the preceding conclusion applies. These latter integrals can be differentiated under the sign, except in the neighbourhood of  $z = 0$ .

**10.50. Integral equations for  $\text{ce}_m(z, q)$ ,  $\text{se}_m(z, q)$  with nucleus  $e^{2ik(\cosh \xi \cos \eta \cos \theta + \sinh \xi \sin \eta \sin \theta)}$ .** It is readily confirmed by substitution that [183]

$$\zeta = \int_0^{2\pi} e^{ik_1(x \cos \theta + y \sin \theta)} f(\theta) d\theta, \quad (1)$$

$f(\theta)$  being an arbitrary differentiable function of  $\theta$ , is a solution of

$$\frac{\partial^2 \zeta}{\partial x^2} + \frac{\partial^2 \zeta}{\partial y^2} + k_1^2 \zeta = 0. \quad (2)$$

Introducing elliptical coordinates (Chap. IX), and taking

$$4k^2 = k_1^2 h^2 > 0,$$

(1), (2) become, respectively,

$$\zeta = \int_0^{2\pi} e^{2ikw} f(\theta) d\theta, \quad (3)$$

$$\text{and} \quad \frac{\partial^2 \zeta}{\partial \xi^2} + \frac{\partial^2 \zeta}{\partial \eta^2} + 2k^2 (\cosh 2\xi - \cos 2\eta) \zeta = 0, \quad (4)$$

with  $w = \cosh \xi \cos \eta \cos \theta + \sinh \xi \sin \eta \sin \theta$ . The physical interpretation of (3), (4) deserves to be mentioned. (4) is the equation for propagation of 'elliptical' waves, and (3) is a solution thereof. Now  $e^{2ikw}$  represents a system of omnidirectional plane waves, since  $\theta$  varies from 0 to  $2\pi$ . Hence we may visualize 'elliptical' waves as being synthesized from 'plane' waves moving in all directions ( $\theta$ ) and properly coordinated in amplitude and phase [ $f(\theta)$ ].

As a suitable solution of (4) we take  $\zeta = f_1(\xi)f_2(\eta)$ , where  $f_1, f_2$  are solutions of

$$\frac{d^2 f_1}{d\xi^2} - (a - 2k^2 \cosh 2\xi) f_1 = 0 \quad (5)$$

$$\text{and} \quad \frac{d^2 f_2}{d\eta^2} + (a - 2k^2 \cos 2\eta) f_2 = 0, \quad (6)$$

respectively.

The next step is to define  $f(\theta)$ , so that (3) is a solution of (6) with  $\zeta$  written for  $f_2$ . From (3)

$$\begin{aligned} \frac{d^2 \zeta}{d\eta^2} = & - \int_0^{2\pi} [4k^2 (\sinh \xi \cos \eta \sin \theta - \cosh \xi \sin \eta \cos \theta)^2 + \\ & + 2ik (\cosh \xi \cos \eta \cos \theta + \sinh \xi \sin \eta \sin \theta)] e^{2ikw} f(\theta) d\theta. \end{aligned} \quad (7)$$

Now

$$\begin{aligned} & (\sinh \xi \cos \eta \sin \theta - \cosh \xi \sin \eta \cos \theta)^2 \\ & = (\sinh \xi \sin \eta \cos \theta - \cosh \xi \cos \eta \sin \theta)^2 - \frac{1}{2} (\cos 2\eta - \cos 2\theta). \end{aligned} \quad (8)$$

Substituting from (8) into (7) gives

$$\frac{d^2 \zeta}{d\eta^2} = \int_0^{2\pi} f(\theta) \left[ 2k^2 (\cos 2\eta - \cos 2\theta) + \frac{\partial^2}{\partial \theta^2} \right] e^{2ikw} d\theta. \quad (9)$$

Then by (3), (9)

$$\frac{d^2\zeta}{d\eta^2} + (a - 2k^2 \cos 2\eta)\zeta = \int_0^{2\pi} f(\theta) \left[ a - 2k^2 \cos 2\theta + \frac{\partial^2}{\partial \theta^2} \right] e^{2ikw} d\theta. \quad (10)$$

But

$$\begin{aligned} f(\theta) \frac{\partial^2}{\partial \theta^2} (e^{2ikw}) &= \frac{\partial}{\partial \theta} \left[ f(\theta) \frac{\partial}{\partial \theta} (e^{2ikw}) \right] - \frac{\partial f(\theta)}{\partial \theta} \frac{\partial}{\partial \theta} (e^{2ikw}) \\ &= \frac{\partial}{\partial \theta} \left[ f(\theta) \frac{\partial}{\partial \theta} (e^{2ikw}) - \frac{\partial f(\theta)}{\partial \theta} e^{2ikw} \right] + \frac{\partial^2 f}{\partial \theta^2} e^{2ikw}. \end{aligned} \quad (11)$$

Substituting from (11) into (10) leads to

$$\begin{aligned} \frac{d^2\zeta}{d\eta^2} + (a - 2k^2 \cos 2\eta)\zeta &= \int_0^{2\pi} [f''(\theta) + (a - 2k^2 \cos 2\theta)f(\theta)] e^{2ikw} d\theta + \\ &\quad + \left[ f(\theta) \frac{\partial}{\partial \theta} (e^{2ikw}) - \frac{\partial f(\theta)}{\partial \theta} e^{2ikw} \right]_0^{2\pi} \end{aligned} \quad (12)$$

If  $f(\theta)$  satisfies (6), the first [ ] in (12) vanishes, while if  $f(\theta)$  has period  $\pi$ ,  $2\pi$ , the second [ ] vanishes at the limits. Under these conditions  $\zeta$  satisfies (6) as required, so  $f(\theta)$  must be a multiple of  $\text{ce}_m(\theta, q)$ ,  $\text{se}_m(\theta, q)$ . Also with the same  $a, q$  in (5), (6) it follows that  $f_1(\xi, q) \propto \text{Ce}_m(\xi, q)$  or  $\text{Se}_m(\xi, q)$ , and  $f_2(\eta, q) \propto \text{ce}_m(\eta, q)$  or  $\text{se}_m(\eta, q)$ . Thus (3) yields the integral equations

$$\text{Ce}_m(\xi) \text{ce}_m(\eta) = \rho_m \int_0^{2\pi} e^{2ikw} \text{ce}_m(\theta) d\theta \quad (13)$$

$$\text{and} \quad \text{Se}_m(\xi) \text{se}_m(\eta) = \sigma_m \int_0^{2\pi} e^{2ikw} \text{se}_m(\theta) d\theta. \quad (14)$$

$\rho_m, \sigma_m$  are the characteristic values of the nucleus  $e^{2ikw}$ .

**10.51. Evaluation of (13), (14) § 10.50.** We commence by writing

$$2kw = 2k(x_1 \cos \theta + y_1 \sin \theta) = z_1 \cos(\theta - \alpha), \quad (1)$$

where

$$x_1 = x/h = \cosh \xi \cos \eta, \quad y_1 = y/h = \sinh \xi \sin \eta,$$

$$z_1 = 2k(\cosh^2 \xi \cos^2 \eta + \sinh^2 \xi \sin^2 \eta)^{\frac{1}{2}} = 2k(\cosh^2 \xi - \sin^2 \eta)^{\frac{1}{2}} = k_1 r,$$

and  $\alpha = \tan^{-1}(y_1/x_1)$ , or  $\tan \alpha = \tanh \xi \tan \eta$ . Next we use the expansion [202, p. 43]

$$e^{i[z_1 \cos(\theta - \alpha)]} = J_0(z_1) + 2 \sum_{p=1}^{\infty} i^p \cos p(\theta - \alpha) J_p(z_1), \quad (2)$$

together with that of  $\text{ce}_{2n}(\theta)$ , in the integrand of (13) § 10.50, thereby obtaining

$$\text{Ce}_{2n}(\xi)\text{ce}_{2n}(\eta) = \rho_{2n} \int_0^{2\pi} \left[ J_0(z_1) + 2 \sum_{p=1}^{\infty} i^p \cos p(\theta - \alpha) J_p(z_1) \right] \times \\ \times \sum_{r=0}^{\infty} A_{2r}^{(2n)} \cos 2r\theta \, d\theta. \quad (3)$$

Now

$$\int_0^{2\pi} \left[ J_0(z_1) + 2 \sum_{p=1}^{\infty} i^p \cos p(\theta - \alpha) J_p(z_1) \right] \cos 2r\theta \, d\theta = 2\pi i^{2r} \cos 2r\alpha J_{2r}(z_1), \quad (4)$$

the other integrals vanishing by virtue of orthogonality of the circular functions. Also, the series concerned are absolutely and uniformly convergent. Hence by (3), (4) we obtain the result

$$\text{Ce}_{2n}(\xi)\text{ce}_{2n}(\eta) = 2\pi\rho_{2n} \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} \cos 2r\alpha J_{2r}(z_1), \quad (5)$$

this series being absolutely and uniformly convergent. Since the r.h.s. of (3) when evaluated is real, it follows that the imaginary part vanishes, so

$$\int_0^{2\pi} \sin[z_1 \cos(\theta - \alpha)] \text{ce}_{2n}(\theta) \, d\theta = 0. \quad (6)$$

To evaluate  $\rho_{2n}$  in (5), put  $\eta = 0$ , then  $\alpha = 0$  and  $z_1 = 2k \cosh \xi$ , giving

$$\text{Ce}_{2n}(\xi)\text{ce}_{2n}(0) = 2\pi\rho_{2n} \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} J_{2r}(2k \cosh \xi). \quad (7)$$

Thus from (7) above and (15) § 8.10,

$$\rho_{2n} = \text{ce}_{2n}(0, q) \text{ce}_{2n}(\frac{1}{2}\pi, q) / 2\pi A_0^{(2n)} = p_{2n} / 2\pi. \quad (8)$$

Using (8) in (13) § 10.50, and remembering that the imaginary part vanishes by (6), we get the integral equation for  $\text{ce}_{2n}(\eta, q)$ , namely,

$$\text{Ce}_{2n}(\xi)\text{ce}_{2n}(\eta) = \rho_{2n} \int_0^{2\pi} \cos[z_1 \cos(\theta - \alpha)] \text{ce}_{2n}(\theta) \, d\theta \quad (9)$$

$$= p_{2n} \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} \cos 2r\alpha J_{2r}(z_1). \quad (10)$$

**10.52. The remaining integral equations.** Analysis similar to that in § 10.51, using the multipliers  $p_m$ ,  $s_m$  defined in Appendix I, leads to the following:

$$\rho_{2n+1} = p_{2n+1} / 2\pi, \quad (1)^\dagger$$

† When used in (13), (14) § 10.50,  $\rho_{2n+1}$ ,  $\sigma_{2n+1}$  must be multiplied by  $-i$ , since the l.h.s. are real.

$$\text{Ce}_{2n+1}(\xi)\text{ce}_{2n+1}(\eta) = \rho_{2n+1} \int_0^{2\pi} \sin[z_1 \cos(\theta - \alpha)] \text{ce}_{2n+1}(\theta) d\theta \quad (2)$$

$$= -\rho_{2n+1} \sum_{r=0}^{\infty} (-1)^r A_{2r+1}^{(2n+1)} \cos(2r+1)\alpha J_{2r+1}(z_1), \quad (3)$$

$$\int_0^{2\pi} \cos[z_1 \cos(\theta - \alpha)] \text{ce}_{2n+1}(\theta) d\theta = 0. \quad (4)$$

$$\sigma_{2n+1} = s_{2n+1}/2\pi, \quad (5)$$

$$\text{Se}_{2n+1}(\xi)\text{se}_{2n+1}(\eta) = \sigma_{2n+1} \int_0^{2\pi} \sin[z_1 \cos(\theta - \alpha)] \text{se}_{2n+1}(\theta) d\theta \quad (6)$$

$$= s_{2n+1} \sum_{r=0}^{\infty} (-1)^r B_{2r+1}^{(2n+1)} \sin(2r+1)\alpha J_{2r+1}(z_1), \quad (7)$$

$$\int_0^{2\pi} \cos[z_1 \cos(\theta - \alpha)] \text{se}_{2n+1}(\theta) d\theta = 0. \quad (8)$$

$$\sigma_{2n+2} = s_{2n+2}/2\pi, \quad (9)$$

$$\text{Se}_{2n+2}(\xi)\text{se}_{2n+2}(\eta) = \sigma_{2n+2} \int_0^{2\pi} \cos[z_1 \cos(\theta - \alpha)] \text{se}_{2n+2}(\theta) d\theta \quad (10)$$

$$= -s_{2n+2} \sum_{r=0}^{\infty} (-1)^r B_{2r+2}^{(2n+2)} \sin(2r+2)\alpha J_{2r+2}(z_1), \quad (11)$$

$$\int_0^{2\pi} \sin[z_1 \cos(\theta - \alpha)] \text{se}_{2n+2}(\theta) d\theta = 0. \quad (12)$$

By analysis similar to that in § 8.50 it may be shown that the series herein and in § 10.51 are absolutely and uniformly convergent in any finite region of the  $z$ -plane.

### 10.53. Expansions of $\frac{\cos}{\sin} \{2k(\cosh \xi \cos \eta \cos \theta + \sinh \xi \sin \eta \sin \theta)\}$ ,

$k^2 > 0$ . Assume that

$$\begin{aligned} & \cos[z_1 \cos(\theta - \alpha)] \\ &= \sum_{m=0}^{\infty} [C_{2m}(\eta) \text{Ce}_{2m}(\xi) \text{ce}_{2m}(\theta) + S_{2m+2}(\eta) \text{Se}_{2m+2}(\xi) \text{se}_{2m+2}(\theta)]. \end{aligned} \quad (1)$$

Multiply both sides by  $\text{ce}_{2n}(\theta)$ , integrate with respect to  $\theta$  from 0 to  $2\pi$ , and we get

$$\int_0^{2\pi} \cos[z_1 \cos(\theta - \alpha)] \text{ce}_{2n}(\theta) d\theta = \pi C_{2n}(\eta) \text{Ce}_{2n}(\xi), \quad (2)$$

the other integrals vanishing by virtue of orthogonality (§ 2.19). From (2) above, (8), (9) § 10.51, it follows that

$$C_{2n}(\eta) = 2 \operatorname{ce}_{2n}(\eta)/p_{2n}. \quad (3)$$

Multiplying both sides of (1) by  $\operatorname{se}_{2n+2}(\theta)$  and proceeding as before, we get

$$S_{2n+2}(\eta) = 2 \operatorname{se}_{2n+2}(\eta)/s_{2n+2}. \quad (4)$$

Substituting (3), (4) into (1) yields the expansion

$$\begin{aligned} & \cos\{2k(\cosh \xi \cos \eta \cos \theta + \sinh \xi \sin \eta \sin \theta)\} \\ &= 2 \sum_{n=0}^{\infty} \left[ \frac{\operatorname{Ce}_{2n}(\xi) \operatorname{ce}_{2n}(\eta) \operatorname{ce}_{2n}(\theta)}{p_{2n}} + \frac{\operatorname{Se}_{2n+2}(\xi) \operatorname{se}_{2n+2}(\eta) \operatorname{se}_{2n+2}(\theta)}{s_{2n+2}} \right]. \quad (5) \end{aligned}$$

By similar analysis we find that

$$\begin{aligned} & \sin\{2k(\cosh \xi \cos \eta \cos \theta + \sinh \xi \sin \eta \sin \theta)\} \\ &= 2 \sum_{n=0}^{\infty} \left[ \frac{\operatorname{Ce}_{2n+1}(\xi) \operatorname{ce}_{2n+1}(\eta) \operatorname{ce}_{2n+1}(\theta)}{p_{2n+1}} + \frac{\operatorname{Se}_{2n+1}(\xi) \operatorname{se}_{2n+1}(\eta) \operatorname{se}_{2n+1}(\theta)}{s_{2n+1}} \right]. \quad (6) \end{aligned}$$

In (5), (6) write  $i\xi$  for  $\xi$ , then, referring to § 10.60, the r.h.s. of (5) above reduces to the form (7) for  $\theta = 0$ , and to (8) for  $\theta = \frac{1}{2}\pi$ , while (6) above reduces to the form (9) for  $\theta = 0$ , and to (10) for  $\theta = \frac{1}{2}\pi$ . Accordingly we obtain the expansion

$$\begin{aligned} & e^{ik_1 \cos(\theta - \alpha)} \\ &= e^{ik_1(x \cos \theta + y \sin \theta)} = \cos\{k_1(x \cos \theta + y \sin \theta)\} + i \sin\{k_1(x \cos \theta + y \sin \theta)\} \\ &= 2 \sum_{n=0}^{\infty} \left[ \frac{1}{p_{2n}} \operatorname{Ce}_{2n}(\xi) \operatorname{ce}_{2n}(\eta) \operatorname{ce}_{2n}(\theta) + \frac{1}{s_{2n+2}} \operatorname{Se}_{2n+2}(\xi) \operatorname{se}_{2n+2}(\eta) \operatorname{se}_{2n+2}(\theta) + \right. \\ & \quad \left. + i \left\{ \frac{1}{p_{2n+1}} \operatorname{Ce}_{2n+1}(\xi) \operatorname{ce}_{2n+1}(\eta) \operatorname{ce}_{2n+1}(\theta) + \right. \right. \\ & \quad \left. \left. + \frac{1}{s_{2n+1}} \operatorname{Se}_{2n+1}(\xi) \operatorname{se}_{2n+1}(\eta) \operatorname{se}_{2n+1}(\theta) \right\} \right]. \quad (7) \end{aligned}$$

When the fundamental ellipse tends to a circle, it may be shown, by aid of Appendix I, that with  $\theta = 0, \frac{1}{2}\pi$ , (5), (6) degenerate to well-known expansions in B.F.

### 10.60. Expansions of nuclei in characteristic functions, $q > 0$ .

If in (2) § 10.11 we put  $\chi = R(u)S(z)$ , and proceed as in § 9.21, we obtain the two ordinary equations

$$\frac{d^2 R}{du^2} + (a - 2q \cos 2u)R = 0 \quad (1)$$

and 
$$\frac{d^2 S}{dz^2} + (a - 2q \cos 2z)S = 0. \quad (2)$$

For a given value of  $q$ , if  $a = a_m$ , the products of the first solutions of (1), (2) are  $\chi_{mc} = c_m \text{ce}_m(u) \text{ce}_m(z)$ , while if  $a = b_m$  we have

$$\chi_{ms} = s_m \text{se}_m(u) \text{se}_m(z),$$

$c_m$  and  $s_m$  being arbitrary constants,  $m$  taking positive integral values. Hence we may write

$$\chi = \sum_{m=0}^{\infty} c_m \text{ce}_m(u) \text{ce}_m(z) + \sum_{m=1}^{\infty} s_m \text{se}_m(u) \text{se}_m(z). \quad (3)$$

Now  $\chi = e^{2ik \cos u \cos z}$  and  $e^{-2ks \sin u \sin z}$  are also solutions of (2) § 10.11. It appears, then, that these composite integral function solutions may be expressed in infinite series of periodic Mathieu functions. The real part of the first, being even in  $u, z$ , is the nucleus for  $\text{ce}_{2n}(z, q)$ . Now the second series on the r.h.s. of (3) is odd in  $u, z$ , while  $\text{ce}_{2n}(z, q)$  has period  $\pi$ . Let us assume, then, that

$$\cos(2k \cos u \cos z) = \sum_{s=0}^{\infty} c_{2s} \text{ce}_{2s}(u) \text{ce}_{2s}(z), \quad (4)$$

the r.h.s. of which is even in  $u, z$  and admits the period  $\pi$  in both variables. To determine  $c_{2s}$  multiply both sides of (4) by  $\text{ce}_{2n}(u)$  and integrate with respect to  $u$  from 0 to  $\pi$ . Then

$$\int_0^{\pi} \cos(2k \cos u \cos z) \text{ce}_{2n}(u) du = c_{2n} \text{ce}_{2n}(z) \int_0^{\pi} \text{ce}_{2n}^2(u) du, \quad (5)$$

all other terms on the r.h.s. vanishing by virtue of orthogonality (§ 2.19). Hence by (5) above and (1) § 10.12,

$$\text{ce}_{2n}(z)/\lambda_{2n} = \frac{1}{2} \pi c_{2n} \text{ce}_{2n}(z),$$

so, using (5) § 10.12,

$$c_{2n} = 2/\pi \lambda_{2n} = 2A_0^{(2n)}/\text{ce}_{2n}(\frac{1}{2}\pi, q). \quad (6)$$

Consequently from (4), (6) we obtain

$$\cos(2k \cos u \cos z) = 2 \sum_{n=0}^{\infty} \frac{A_0^{(2n)}}{\text{ce}_{2n}(\frac{1}{2}\pi, q)} \text{ce}_{2n}(u) \text{ce}_{2n}(z), \quad (7)$$

which is the expansion of the nucleus for  $\text{ce}_{2n}(z, q)$  in terms of the functions themselves. The seven remaining primary nuclei in

Table 14 may be expanded in a similar way, and the results are given below [97]:

$$\cosh(2k \sin u \sin z) = 2 \sum_{n=0}^{\infty} \frac{A_0^{(2n)}}{ce_{2n}(0)} ce_{2n}(u) ce_{2n}(z), \quad (8)$$

$$\sin(2k \cos u \cos z) = -2k \sum_{n=0}^{\infty} \frac{A_1^{(2n+1)}}{ce'_{2n+1}(\frac{1}{2}\pi)} ce_{2n+1}(u) ce_{2n+1}(z), \quad (9)$$

$$\sinh(2k \sin u \sin z) = 2k \sum_{n=0}^{\infty} \frac{B_1^{(2n+1)}}{se_{2n+1}(0)} se_{2n+1}(u) se_{2n+1}(z), \quad (10)$$

$$\cos u \cos z \cosh(2k \sin u \sin z) = \sum_{n=0}^{\infty} \frac{A_1^{(2n+1)}}{ce_{2n+1}(0)} ce_{2n+1}(u) ce_{2n+1}(z), \quad (11)$$

$$\sin u \sin z \cos(2k \cos u \cos z) = \sum_{n=0}^{\infty} \frac{B_1^{(2n+1)}}{se_{2n+1}(\frac{1}{2}\pi)} se_{2n+1}(u) se_{2n+1}(z), \quad (12)$$

$$\sin u \sin z \sinh(2k \cos u \cos z) = -k \sum_{n=0}^{\infty} \frac{B_2^{(2n+2)}}{se'_{2n+2}(\frac{1}{2}\pi)} se_{2n+2}(u) se_{2n+2}(z), \quad (13)$$

$$\cos u \cos z \sinh(2k \sin u \sin z) = k \sum_{n=0}^{\infty} \frac{B_2^{(2n+2)}}{se_{2n+2}(0)} se_{2n+2}(u) se_{2n+2}(z). \quad (14)$$

By writing  $iz$  for  $z$  in the above relationships, series are obtained in terms of Mathieu and modified Mathieu functions. For  $z$  real, convergence of the series follows from the fact that the  $A, B \rightarrow 0$  as  $n \rightarrow +\infty$  (see § 3.35).

**10.61. Results deducible from § 10.60.** Writing  $u = \frac{1}{2}\pi$  in (7) § 10.60 yields

$$1 = 2 \sum_{n=0}^{\infty} A_0^{(2n)} ce_{2n}(z). \quad (1)$$

Assuming the r.h.s. of (9) § 10.60 and its first derivative are uniformly convergent with respect to  $u$ , by differentiating and substituting  $u = \frac{1}{2}\pi$  we get

$$\cos z = \sum_{n=0}^{\infty} A_1^{(2n+1)} ce_{2n+1}(z). \quad (2)$$

In a similar way we find that

$$\sin z = \sum_{n=0}^{\infty} B_1^{(2n+1)} se_{2n+1}(z), \quad (3)$$

$$\sin 2z = \sum_{n=0}^{\infty} B_2^{(2n+2)} se_{2n+2}(z). \quad (4)$$

Inserting the expansion of  $\text{ce}_{2n}(z)$  in (1) gives

$$1 = 2 \sum_{n=0}^{\infty} A_0^{(2n)} \sum_{r=0}^{\infty} A_{2r}^{(2n)} \cos 2rz. \quad (5)$$

Since the l.h.s. is independent of  $z$ , equating constant terms, i.e.  $r = 0$ , yields

$$1 = 2 \sum_{n=0}^{\infty} [A_0^{(2n)}]^2. \quad (6)$$

Equating the coefficient of  $\cos 2rz$  to zero leads to

$$\sum_{n=0}^{\infty} A_0^{(2n)} A_{2r}^{(2n)} = 0 \quad (r \neq 0). \quad (7)$$

Similarly we deduce that

$$\sum_{n=0}^{\infty} [A_1^{(2n+1)}]^2 = \sum_{n=0}^{\infty} [B_1^{(2n+1)}]^2 = \sum_{n=0}^{\infty} [B_2^{(2n+2)}]^2 = 1. \quad (8)$$

Using the orthogonal properties of the functions the following expansions may be obtained:

$$\cos 2rz = \sum_{n=0}^{\infty} A_{2r}^{(2n)} \text{ce}_{2n}(z), \quad (9)$$

$$\cos(2r+1)z = \sum_{n=0}^{\infty} A_{2r+1}^{(2n+1)} \text{ce}_{2n+1}(z), \quad (10)$$

$$\sin(2r+1)z = \sum_{n=0}^{\infty} B_{2r+1}^{(2n+1)} \text{se}_{2n+1}(z), \quad (11)$$

$$\sin(2r+2)z = \sum_{n=0}^{\infty} B_{2r+2}^{(2n+2)} \text{se}_{2n+2}(z), \quad (12)$$

$$\sum_{\substack{n=0 \\ r>0}}^{\infty} [A_{2r}^{(2n)}]^2 = \sum_{n=0}^{\infty} [A_{2r+1}^{(2n+1)}]^2 = \sum_{n=0}^{\infty} [B_{2r+1}^{(2n+1)}]^2 = \sum_{n=0}^{\infty} [B_{2r+2}^{(2n+2)}]^2 = 1, \quad (13)$$

$$\begin{aligned} \sum_{n=0}^{\infty} [A_{2r}^{(2n)} A_{2s}^{(2n)}] &= \sum_{n=0}^{\infty} [A_{2r+1}^{(2n+1)} A_{2s+1}^{(2n+1)}] = \sum_{n=0}^{\infty} [B_{2r+1}^{(2n+1)} B_{2s+1}^{(2n+1)}] \\ &= \sum_{n=0}^{\infty} [B_{2r+2}^{(2n+2)} B_{2s+2}^{(2n+2)}] = 0 \end{aligned} \quad (14)$$

provided  $r \neq s$ . Additional relationships between the functions of integral order will be found in reference [97].

**10.62. Additional expansions.** Assuming uniform convergence of the series in § 10.60, numerous results may be deduced by differentiating or by integrating term by term. Two examples involving B.F. will suffice to illustrate this point. Integrate both sides of (7) § 10.60 with respect to  $u$  from 0 to  $\pi$ , and we get

$$1^{\circ}. \quad J_0(2k \cos z) = 2 \sum_{n=0}^{\infty} [A_0^{(2n)}]^2 \text{ce}_{2n}(z, q) / \text{ce}_{2n}(\tfrac{1}{2}\pi, q). \quad (1)$$

$$\text{If } z = 0, \quad J_0(2k) = 2 \sum_{n=0}^{\infty} [A_0^{(2n)}]^2 \text{ce}_{2n}(0, q) / \text{ce}_{2n}(\tfrac{1}{2}\pi, q); \quad (2)$$

$$\text{while for } z = \tfrac{1}{2}\pi \quad 1 = 2 \sum_{n=0}^{\infty} [A_0^{(2n)}]^2, \quad (3)$$

as at (6) § 10.61.

2°. Multiplying both sides of (7) § 10.60 by  $\cos 2mu$  and integrating as before leads to

$$J_{2m}(2k \cos z) = \sum_{n=0}^{\infty} A_0^{(2n)} A_{2m}^{(2n)} \text{ce}_{2n}(z, q) / \text{ce}_{2n}(\tfrac{1}{2}\pi, q) \quad (m > 0). \quad (4)$$

Rigorous proofs of the validity of results in §§ 10.53, 10.60, 10.61, and a demonstration that, under conditions similar to those for the Fourier case, a function of period  $\pi$ ,  $2\pi$  may be expanded in a series of Mathieu functions of integral order, are beyond the scope of the text. For functions having period  $2s\pi$ ,  $s \geq 2$ , the Mathieu functions of order  $2n + \beta$ ,  $2n + 1 + \beta$ ,  $\beta = p/s$ ,  $0 < \beta < 1$ , would be needed (see §§ 2.20, 4.71).

**10.70. Integral equations of the second kind.** We commence with the equation

$$\frac{d^2 y}{du^2} + [a - 2q\psi(\omega u)]y = 0, \quad (1)$$

where  $\psi(\omega u)$  has the same properties as in (1) § 6.10.

Multiplying throughout by  $\sin \nu u$ ,  $\nu^2 = a$ , gives

$$\sin \nu u y'' + a \sin \nu u y = 2q\psi(\omega u) \sin \nu u y, \quad (2)$$

$$\text{so} \quad \int_0^z \sin \nu u dy' + a \int_0^z \sin \nu u y du = 2q \int_0^z \psi(\omega u) \sin \nu u y du. \quad (3)$$

Thus

$$[y' \sin \nu u]_0^z - \nu \int_0^z \cos \nu u dy + a \int_0^z \sin \nu u y du = 2q \int_0^z \psi(\omega u) \sin \nu u y du, \quad (4)$$

and ultimately, since  $a = \nu^2$ , we get

$$y'(z) \sin \nu z - \nu y(z) \cos \nu z = -\nu y(0) + 2q \int_0^z \psi(\omega u) \sin \nu u y du. \quad (5)$$

If in (2)  $\sin \nu u$  is replaced by  $\cos \nu u$ , the equation corresponding to (5) is

$$y'(z) \cos \nu u + \nu y(z) \sin \nu z = y'(0) + 2q \int_0^z \psi(\omega u) \cos \nu u y du. \quad (6)$$

Multiplying (5) by  $\cos \nu z/\nu$ , (6) by  $\sin \nu z/\nu$ , and subtracting the first from the second, yields the integral equation

$$y(z) = y(0)\cos \nu z + \frac{y'(0)\sin \nu z}{\nu} + \frac{2q}{\nu} \int_0^z \sin \nu(z-u)\psi(\omega u)y(u) du. \quad (7)$$

Hence we are led to two solutions of (1), in the form of the integral equations of the second kind with variable upper limits, namely,

$$y_1(z) = y_1(0)\cos \nu z + \frac{y_1'(0)\sin \nu z}{\nu} + \frac{2q}{\nu} \int_0^z \sin \nu(z-u)\psi(\omega u)y_1(u) du, \quad (8)$$

and

$$y_2(z) = y_2(0)\cos \nu z + \frac{y_2'(0)\sin \nu z}{\nu} + \frac{2q}{\nu} \int_0^z \sin \nu(z-u)\psi(\omega u)y_2(u) du. \quad (9)$$

If we specify the initial conditions, as in § 4.10, to be

$$y_1(0) = 1, \quad y_1'(0) = 0,$$

$$y_2(0) = 0, \quad y_2'(0) = 1,$$

(8), (9) give

$$y_1(z) = \cos \nu z + \frac{2q}{\nu} \int_0^z \sin \nu(z-u)\psi(\omega u)y_1(u) du \quad (10)$$

and

$$y_2(z) = \frac{\sin \nu z}{\nu} + \frac{2q}{\nu} \int_0^z \sin \nu(z-u)\psi(\omega u)y_2(u) du, \quad (11)$$

respectively. For Mathieu's equation  $\psi(\omega u) = \cos 2u$ .

**10.71. Integral equations for  $y'' - (a - 2q \cosh 2z)y = 0$ .** Using the procedure in § 10.70 but with  $\sinh \nu u$ ,  $\cosh \nu u$  for  $\sin \nu u$ , and  $\cos \nu u$ , respectively, we get

$$y(z) = y(0)\cosh \nu z + \frac{y'(0)\sinh \nu z}{\nu} - \frac{2q}{\nu} \int_0^z \sinh \nu(z-u)\cosh 2u y(u) du. \quad (1)$$

For the initial conditions in § 10.70, (1) yields

$$y_1(z) = \cosh \nu z - \frac{2q}{\nu} \int_0^z \sinh \nu(z-u)\cosh 2u y_1(u) du \quad (z \text{ finite}) \quad (2)$$

and

$$y_2(z) = \frac{\sinh \nu z}{\nu} - \frac{2q}{\nu} \int_0^z \sinh \nu(z-u)\cosh 2u y_2(u) du \quad (z \text{ finite}), \quad (3)$$

where  $y_1(z)$ ,  $y_2(z)$  are, respectively, even and odd solutions of the above differential equation.

**10.72. Solution of (10), (11) § 10.70.** Write  $p = 2q/\nu$ , and assume that

$$y_1(z) = \cos \nu z + pc_1(z) + p^2 c_2(z) + p^3 c_3(z) + \dots, \quad (1)$$

the  $c$  being continuous functions of  $z$ . Substituting (1) into (10) § 10.70 we get

$$pc_1(z) + p^2 c_2(z) + \dots = p \int_0^z \sin \nu(z-u) \psi(\omega u) [\cos \nu u + pc_1(u) + p^2 c_2(u) + \dots] du. \quad (2)$$

Equating the coefficients of  $p$  on each side of (2), we have

$$\begin{aligned} c_1(z) &= \int_0^z \sin \nu(z-u) \cos \nu u \psi(\omega u) du \\ &= \frac{1}{2} \int_0^z [\sin \nu(z-2u) + \sin \nu z] \psi(\omega u) du \\ &= \frac{1}{2} \sin \nu z \int_0^z \psi(\omega u) du + \frac{1}{2} \int_0^z \sin \nu(z-2u) \psi(\omega u) du. \end{aligned} \quad (3)$$

This is now substituted for  $c_1(u)$  into the r.h.s. of (2) and  $c_2(z)$  obtained by equating the coefficients of  $p^2$  on each side. If  $p$  and  $p|\psi(\omega u)|$  are small enough, a first approximation is given by

$$y_1(z) \simeq \cos \nu z + (q/\nu) \left[ \sin \nu z \int_0^z \psi(\omega u) du + \int_0^z \sin \nu(z-2u) \psi(\omega u) du \right], \quad (4)$$

the omitted part being  $O(1/\nu^2)$ . Similarly for (11) § 10.70, we find that

$$y_2(z) \simeq \frac{\sin \nu z}{\nu} - (q/\nu^2) \left[ \cos \nu z \int_0^z \psi(\omega u) du - \int_0^z \cos \nu(z-2u) \psi(\omega u) du \right], \quad (5)$$

the omitted part being  $O(1/\nu^3)$ .

**10.73. Alternative forms of (7) § 10.70.** This may be written

$$y(z) = C_\nu \cos \nu z + S_\nu \sin \nu z + \frac{2q}{\nu} \int_0^z \sin \nu(z-u) \psi(\omega u) y(u) du, \quad (1)$$

where  $C_\nu = y(0)$ ,  $S_\nu = y'(0)/\nu$ . Now let  $a = m^2 + \lambda^2$ ,  $m$  being an integer, then (1) § 10.70 becomes either

$$\frac{d^2 y}{dz^2} + [m^2 - \{\lambda^2 + 2q \psi(\omega z)\}] y = 0 \quad (2)$$

or

$$\frac{d^2 y}{dz^2} + [\lambda^2 - \{2q \psi(\omega z) - m^2\}] y = 0. \quad (3)$$

Since (1) is an integral equation for (1) § 10.70, it follows that the integral equations of the second kind for (2), (3) are, respectively,

$$y(z) = C_m \cos mz + S_m \sin mz + \frac{1}{m} \int_0^z \sin m(z-u) [2q\psi(\omega u) - \lambda^2] y(u) du, \quad (4)$$

$$y(z) = C_\lambda \cos \lambda z + S_\lambda \sin \lambda z + \frac{1}{\lambda} \int_0^z \sin \lambda(z-u) [2q\psi(\omega u) - m^2] y(u) du. \quad (5)$$

Alternatively, if we take  $a = \alpha_1^2 + \alpha_2^2$ , by varying either  $\alpha_1$  or  $\alpha_2$ , keeping  $a$  constant, we can write down an infinite number of integral equations. The  $C, S$  are functions of  $q$ .

#### 10.74. Integro-differential equations for

$$y'' + 2\kappa y' + [a - 2q\psi(\omega z)]y = 0.$$

The integro-differential equations corresponding to (1), (4), (5) § 10.73 are, respectively,

$$y(z) = \bar{C}_\nu \cos \nu z + \bar{S}_\nu \sin \nu z + \frac{1}{\nu} \int_0^z \sin \nu(z-u) \left[ 2q\psi(\omega u) - 2\kappa \frac{d}{du} \right] y(u) du, \quad (1)$$

$$y(z) = \bar{C}_m \cos mz + \bar{S}_m \sin mz + \frac{1}{m} \int_0^z \sin m(z-u) \left[ 2q\psi(\omega u) - \lambda^2 - 2\kappa \frac{d}{du} \right] y(u) du, \quad (2)$$

and

$$y(z) = \bar{C}_\lambda \cos \lambda z + \bar{S}_\lambda \sin \lambda z + \frac{1}{\lambda} \int_0^z \sin \lambda(z-u) \left[ 2q\psi(\omega u) - m^2 - 2\kappa \frac{d}{du} \right] y(u) du. \quad (3)$$

The  $\bar{C}, \bar{S}$  are functions of  $q$ .

**10.75. Second solution of Mathieu's equation using (4) § 10.73.** The integral equation may be split up into the two parts, namely,

$$y_1(z) = C_m \cos mz + \frac{1}{m} \int_0^z \sin m(z-u) (2q \cos 2u - \lambda^2) y_1(u) du \quad (1)$$

and

$$y_2(z) = S_m \sin mz + \frac{1}{m} \int_0^z \sin m(z-u) (2q \cos 2u - \lambda^2) y_2(u) du. \quad (2)$$

Let  $a$  be the characteristic number for  $ce_2(z, q)$ , then we have to determine  $y_2(z)$  from (2). For  $ce_2(z, q)$ , by (5) § 2.151

$$a = 4 + \frac{5}{12}q^2 - \frac{763}{13824}q^4 + \dots, \quad (3)$$

$$\text{so with } m = 2, \quad \lambda^2 = \frac{5}{12}q^2 - \frac{763}{13824}q^4 + \dots \quad (4)$$

Assume that

$$y_2(u) = s_0(u) + qs_1(u) + q^2s_2(u) + \dots, \quad (5)$$

$$S_2(q) = 1 + \beta_1q + \beta_2q^2 + \beta_3q^3 + \dots \quad (6)$$

Substituting (4), (5), (6) into (2) gives

$$\begin{aligned} s_0(z) + qs_1(z) + q^2s_2(z) + q^3s_3(z) + \dots &= (1 + \beta_1q + \beta_2q^2 + \beta_3q^3 + \dots)\sin 2z + \\ &+ \int_0^z \sin 2(z-u) \left[ q \cos 2u - \frac{5}{24}q^2 + \frac{763}{27648}q^4 - \dots \right] \times \\ &\times [s_0(u) + qs_1(u) + q^2s_2(u) + \dots] du. \quad (7) \end{aligned}$$

Equating like powers of  $q$  on both sides of (7) leads to

$$q^0 \quad s_0(z) = \sin 2z, \quad (8)$$

$$\begin{aligned} q \quad s_1(z) &= \beta_1 \sin 2z + \int_0^z \sin 2(z-u) \cos 2u s_0(u) du \\ &= \beta_1 \sin 2z + \frac{1}{2} \int_0^z \sin 2(z-u) \sin 4u du \\ &= (\beta_1 + \frac{1}{8}) \sin 2z - \frac{1}{12} \sin 4z. \quad (9) \end{aligned}$$

If for the sake of illustration we adopt the normalization of § 2.11, the coefficient of  $\sin 2z$  is unity for all  $q$ . Thus in  $s_1(z)$ ,  $s_2(z)$ , ... the coefficient of  $\sin 2z$  must vanish, so

$$\beta_1 = -\frac{1}{8} \quad \text{and} \quad s_1(z) = -\frac{1}{12} \sin 4z; \quad (10)$$

$$\begin{aligned} q^2 \quad s_2(z) &= \beta_2 \sin 2z + \int_0^z \sin 2(z-u) \left[ \cos 2u s_1(u) - \frac{5}{24} s_0(u) \right] du \\ &= \beta_2 \sin 2z - \int_0^z \sin 2(z-u) \left[ \frac{1}{12} \cos 2u \sin 4u + \frac{5}{24} \sin 2u \right] du \\ &= \left( \beta_2 - \frac{9}{128} \right) \sin 2z + \frac{1}{8} z \cos 2z + \frac{1}{384} \sin 6z. \quad (11) \end{aligned}$$

Thus  $\beta_2 = \frac{9}{128}$  and  $s_2(z) = \frac{1}{8}z \cos 2z + \frac{1}{384} \sin 6z$ . (12)

$$q^3 s_3(z) = \left( \beta_3 - \frac{619}{34560} \right) \sin 2z - \left[ -\frac{1}{32}z + \frac{1}{96}z \cos 4z - \frac{53}{13824} \sin 4z + \frac{1}{23040} \sin 8z \right],$$

giving  $\beta_3 = \frac{619}{34560}$ ,

and

$$s_3(z) = - \left[ -\frac{1}{32}z + \frac{1}{96}z \cos 4z - \frac{53}{13824} \sin 4z + \frac{1}{23040} \sin 8z \right], \quad (13)$$

and so on. Then

$$y_2(z) = \sum_{r=0}^{\infty} q^r s_r(z) = \sin 2z - \frac{1}{12}q \sin 4z + q^2 \left( \frac{1}{8}z \cos 2z + \frac{1}{384} \sin 6z \right) - q^3 \left( -\frac{1}{32}z + \frac{1}{96}z \cos 4z - \frac{53}{13824} \sin 4z + \frac{1}{23040} \sin 8z \right) + \dots \quad (14)$$

Thus

$$y_2(z) = f e_2(z, q) = \frac{1}{8}q^2 \left( 1 - \frac{17}{144}q^2 - \dots \right) z c e_2(z, q) + \sin 2z - \frac{1}{12}q \sin 4z + \frac{1}{384}q^2 \sin 6z - \frac{1}{512}q^3 \left( -\frac{53}{27} \sin 4z + \frac{1}{45} \sin 8z \right) + \dots \quad (15)$$

$$= \left( 1 - \frac{1}{6}q + \frac{9}{128}q^2 + \frac{619}{34560}q^3 - \dots \right) \sin 2z + \int_0^z \sin 2(z-u) \left[ q \cos 2u - \frac{5}{24}q^2 + \frac{763}{27648}q^4 - \dots \right] f e_2(u, q) du. \quad (16)$$

A similar treatment of equation (1) would yield the series for  $c e_2(z, q)$ , the first solution of Mathieu's equation with  $a = a_2$ , as given at (3) § 2.150. In general, if  $y_1(z) = c e_m(z, q)$  and the  $q$  series for  $a$  is unknown, write

$$a = m^2 + \alpha_1 q + \alpha_2 q^2 + \alpha_3 q^3 + \dots, \quad (17)$$

make the coefficient of  $\cos mz$  unity, and determine  $\alpha_1, \alpha_2, \dots$  so that all terms in the expansion are periodic in  $\pi$  or  $2\pi$ , according as  $m$  is even or odd (see § 2.13 et seq.). To obtain  $s e_m(z, q)$ , treat (2) in this way.  $g e_m(z, q)$  can be obtained by analysis similar to that from (3)-(15).

**10.76. Integral equations for  $y_1(z)y_2(z)$ .** Let  $y_1(z)$ ,  $y_2(z)$  be independent solutions of

$$y'' + (a - 2q \cos 2u)y = 0, \quad (1)$$

for the same  $a$ ,  $q$ . Then writing  $\xi(u) = (2q \cos 2u - a)$ , we have

$$y_1'' - \xi(u)y_1 = 0 \quad (2)$$

and

$$y_2'' - \xi(u)y_2 = 0. \quad (3)$$

Multiplying (2) by  $y_2'$ , (3) by  $y_1'$ , adding and integrating with respect to  $u$  from 0 to  $z$ , gives

$$\int_0^z (y_1'' y_2' + y_1' y_2'') du = \int_0^z (y_1' y_2' + y_2' y_1') \xi(u) du, \quad (4)$$

$$\text{so} \quad \int_0^z d(y_1' y_2') = \int_0^z \xi(u) d(y_1 y_2). \quad (5)$$

Hence by partial integration of the r.h.s. of (5) we find that

$$\begin{aligned} y_1'(z)y_2'(z) &= y_1'(0)y_2'(0) - y_1(0)y_2(0)\xi(0) + \\ &\quad + y_1(z)y_2(z)\xi(z) + 4q \int_0^z y_1(u)y_2(u)\sin 2u du. \end{aligned} \quad (6)$$

If the initial conditions are  $y_1(0) = y_2'(0) = 1$ ,  $y_1'(0) = y_2(0) = 0$ , the first two members on the r.h.s. of (6) vanish, and we obtain

$$y_1'(z)y_2'(z) = y_1(z)y_2(z)\xi(z) + 4q \int_0^z y_1(u)y_2(u)\sin 2u du. \quad (7)$$

Results similar to (6), (7) may be obtained in connexion with Hill's equation.

For the equation  $y'' - (a - 2q \cosh 2u)y = 0$ , with

$$\chi(u) = (2q \cosh 2u - a)$$

we get

$$\begin{aligned} y_1'(z)y_2'(z) &= y_1'(0)y_2'(0) + y_1(0)y_2(0)\chi(0) - \\ &\quad - y_1(z)y_2(z)\chi(z) + 4q \int_0^z y_1(u)y_2(u)\sinh 2u du. \end{aligned} \quad (8)$$

**10.77. Differential equation satisfied by  $w(z) = y_1(z)y_2(z)$ .** Mathieu's equation may be written

$$y'' - \xi y = 0, \quad (1)$$

where  $\xi = (2q \cos 2z - a)$ . Differentiating (1) gives  $y''' - \xi y' - \xi' y = 0$ ,

so

$$y_1''' - \xi y_1' - \xi' y_1 = 0 \quad (2)$$

and

$$y_2''' - \xi y_2' - \xi' y_2 = 0. \quad (3)$$

Multiplying (2) by  $y_2$ , (3) by  $y_1$ , and adding leads to the equation

$$y_1'''y_2 + y_2'''y_1 - 2\xi'y_1y_2 - \xi(y_1y_2' + y_2y_1') = 0. \quad (4)$$

From (1) we have

$$(y_1'' - \xi y_1)y_2' = 0 \quad (5)$$

and

$$(y_2'' - \xi y_2)y_1' = 0, \quad (6)$$

so by addition

$$y_1''y_2' + y_2''y_1' = \xi(y_1y_2' + y_2y_1') = \xi w'. \quad (7)$$

Also

$$w''' = y_1'''y_2 + y_2'''y_1 + 3(y_1''y_2' + y_2''y_1'). \quad (8)$$

Hence from (4), (7), (8) the equation sought is

$$w''' - 4\xi w' - 2\xi'w = 0. \quad (9)$$

This result applies to Hill's equation (1) § 6.10, provided

$$\xi = [2q\psi(\omega z) - a].$$

The complete solution of (9) with three arbitrary constants is

$$w = Ay_1^2 + By_1y_2 + Cy_2^2. \quad (10)$$

# XI

## ASYMPTOTIC FORMULAE

**11.10. Approximations.** The modified Mathieu functions lend themselves readily to the derivation of approximate asymptotic formulae when  $R(z)$  is large and positive. If  $k$  and  $z$  are such that  $2k \cosh z \simeq ke^z = v$ , this being appreciably greater than the order of the function, the dominant term in the asymptotic expansion of  $J_{2r}(2k \cosh z)$  is [202, p. 158]

$$(2/\pi v)^{\frac{1}{2}} \cos(v - \frac{1}{4}\pi - r\pi) = (-1)^r (2/\pi v)^{\frac{1}{2}} \sin(v + \frac{1}{4}\pi). \quad (1)$$

Substituting (1) in (15) § 8.10 and using the multipliers  $p_m, s_m$  in Appendix I, leads to the approximate result

$$\text{Ce}_{2n}(z, q) \sim p_{2n} (2/\pi v)^{\frac{1}{2}} \sin(v + \frac{1}{4}\pi) \quad (a_{2n}). \quad (2)$$

Writing

$$\begin{aligned} J_{2r+1}(2k \cosh z) &\sim (2/\pi v)^{\frac{1}{2}} \cos\{v - \frac{1}{4}\pi - \frac{1}{2}(2r+1)\pi\} \\ &= (-1)^{r+1} (2/\pi v)^{\frac{1}{2}} \cos(v + \frac{1}{4}\pi) \end{aligned} \quad (3)$$

in (1) § 8.12 leads to

$$\text{Ce}_{2n+1}(z, q) \sim -p_{2n+1} (2/\pi v)^{\frac{1}{2}} \cos(v + \frac{1}{4}\pi) \quad (a_{2n+1}). \quad (4)$$

The same result follows from (2) § 8.12, while (6), (7) § 8.13 give with

$$\tanh z \simeq \coth z \simeq 1, \quad 2k \sinh z \simeq 2k \cosh z \simeq ke^z,$$

$$\text{Se}_{2n+1}(z, q) \sim -s_{2n+1} (2/\pi v)^{\frac{1}{2}} \cos(v + \frac{1}{4}\pi) \quad (b_{2n+1}). \quad (5)$$

From (4), (5) when  $R(z) > 0$  is large enough, it follows that

$$\text{Ce}_{2n+1}(z, q) \sim (p_{2n+1}/s_{2n+1}) \text{Se}_{2n+1}(z, q). \quad (6)$$

From (10), (11) § 8.13 we derive

$$\text{Se}_{2n+2}(z, q) \sim s_{2n+2} (2/\pi v)^{\frac{1}{2}} \sin(v + \frac{1}{4}\pi) \quad (b_{2n+2}), \quad (7)$$

and so by (2), (7), when  $R(z) > 0$  is large enough, we may write

$$\text{Ce}_{2n+2}(z, q) \sim (p_{2n+2}/s_{2n+2}) \text{Se}_{2n+2}(z, q). \quad (8)$$

As  $z$  (large and real) increases, all the above functions, and those at (9)–(12), alternate† with ever-increasing rapidity, but decreasing amplitudes. When  $z \rightarrow +\infty$  they all tend to zero exponentially.

The second solutions corresponding to the first given above are defined in §§ 8.11–8.13. Using the multipliers in Appendix I and

† An alternating function is one which oscillates and has real zeros.

proceeding as at (1)–(4), we obtain the following approximate asymptotic representations:

$$\text{Fey}_{2n}(z, q) \sim -p_{2n} \left( \frac{2}{\pi v} \right)^{\frac{1}{2}} \cos(v + \frac{1}{4}\pi) \quad (a_{2n}), \quad (9)$$

$$\text{Fey}_{2n+1}(z, q) \sim -p_{2n+1} \left( \frac{2}{\pi v} \right)^{\frac{1}{2}} \sin(v + \frac{1}{4}\pi) \quad (a_{2n+1}), \quad (10)$$

$$\text{Gey}_{2n+1}(z, q) \sim -s_{2n+1} \left( \frac{2}{\pi v} \right)^{\frac{1}{2}} \sin(v + \frac{1}{4}\pi) \quad (b_{2n+1}), \quad (11)$$

$$\text{Gey}_{2n+2}(z, q) \sim -s_{2n+2} \left( \frac{2}{\pi v} \right)^{\frac{1}{2}} \cos(v + \frac{1}{4}\pi) \quad (b_{2n+2}). \quad (12)$$

The dominant term in the asymptotic formula for  $\text{Fey}_{2n+2}(z, q)$  is a constant multiple of that of  $\text{Gey}_{2n+2}$ , the constant being  $p_{2n+2}/s_{2n+2}$ . A similar remark applies to (10), (11). These formulae are valid if  $R(v) \rightarrow +\infty$  with  $v$ , so  $-\frac{1}{2}\pi < \text{phase } z < \frac{1}{2}\pi$ .

**11.11. Approximate formulae for  $\text{Me}_m^{(1),(2)}(z, q)$ ,  $\text{Ne}_m^{(1),(2)}(z, q)$ ,  $\text{Fek}_m(z, q)$ ,  $\text{Gek}_m(z, q)$ .** Using the dominant term in the asymptotic expansions of the Hankel functions in § 13.40,† if  $|v| \gg n$  we get:

$$\text{Me}_{2n}^{(1),(2)}(z, q) \sim p_{2n} \left( \frac{2}{\pi v} \right)^{\frac{1}{2}} e^{\pm i(v - \frac{1}{2}\pi)} \quad (a_{2n}), \quad (1)$$

$$\text{Me}_{2n+1}^{(1),(2)}(z, q) \sim p_{2n+1} \left( \frac{2}{\pi v} \right)^{\frac{1}{2}} e^{\pm i(v - \frac{1}{2}\pi)} \quad (a_{2n+1}), \quad (2)$$

$$\text{Ne}_{2n+1}^{(1),(2)}(z, q) \sim s_{2n+1} \left( \frac{2}{\pi v} \right)^{\frac{1}{2}} e^{\pm i(v - \frac{1}{2}\pi)} \quad (b_{2n+1}), \quad (3)$$

$$\text{Ne}_{2n+2}^{(1),(2)}(z, q) \sim s_{2n+2} \left( \frac{2}{\pi v} \right)^{\frac{1}{2}} e^{\pm i(v - \frac{1}{2}\pi)} \quad (b_{2n+2}). \quad (4)$$

Note that (1) is a constant multiple of (4), and (2) of (3).

Applying the relationships in § 13.41 to (1)–(4), formulae for  $\text{Fek}_m(z, q)$ ,  $\text{Gek}_m(z, q)$  are derived immediately. As  $z \rightarrow +\infty$  the first function tends to a constant multiple of the second, for any  $m$ .

**11.12. Formulae for  $q < 0$ .** Using the formulae in § 8.30 and proceeding as in § 11.10, we obtain the following:

$$\text{Ce}_{2n}(z, -q) \sim p'_{2n} e^v / (2\pi v)^{\frac{1}{2}} \quad (a_{2n}), \quad (1)$$

$$\text{Ce}_{2n+1}(z, -q) \sim s'_{2n+1} e^v / (2\pi v)^{\frac{1}{2}} \quad (b_{2n+1}), \quad (2)$$

$$\text{Se}_{2n+1}(z, -q) \sim p'_{2n+1} e^v / (2\pi v)^{\frac{1}{2}} \quad (a_{2n+1}), \quad (3)$$

$$\text{Se}_{2n+2}(z, -q) \sim s'_{2n+2} e^v / (2\pi v)^{\frac{1}{2}} \quad (b_{2n+2}). \quad (4)$$

† Or the formulae in § 11.10, substituted into (1), (2) § 13.40.

These functions are constant multiples of one another, and each tends to  $+\infty$  monotonically as  $z \rightarrow +\infty$ .

The formulae for  $\text{Fek}_{2n}(z, -q)$ ,  $\text{Fek}_{2n+1}(z, -q)$ ,  $\text{Gek}_{2n+1}(z, -q)$ ,  $\text{Gek}_{2n+2}(z, -q)$  are obtained from (1)–(4), respectively, on replacing  $e^v$  by  $e^{-v}$ . Each function tends to zero monotonically as  $z \rightarrow +\infty$ .

All formulae given hitherto in this chapter depend upon  $z$  being large enough for the Bessel functions in §§ 8.10–8.30 to be represented (approximately) by the dominant terms in their asymptotic expansions. We shall now remove this restriction on  $z$ , and establish what may be regarded as accurate asymptotic expansions.

**11.20. Accurate asymptotic expansions in  $z$ .** We commence with the modified Mathieu equation

$$y'' - (a - 2k^2 \cosh 2z)y = 0. \quad (1)$$

If in (1) we write  $x = -ike^z = -iv$ , it becomes [37]

$$\frac{d^2y}{dx^2} + \frac{1}{x} \frac{dy}{dx} - \left(1 + \frac{a}{x^2} + \frac{k^4}{x^4}\right)y = 0. \quad (2)$$

A second transformation is effected by putting  $y = we^x$ , and we now get

$$\frac{d^2w}{dx^2} - \left(2 - \frac{1}{x}\right) \frac{dw}{dx} - \left(1 + \frac{a}{x^2} + \frac{k^4}{x^4}\right)w = 0. \quad (3)$$

To solve (3) assume that  $w = \sum_{r=0}^{\infty} (-1)^r c_r x^{-r-1}$ , with  $c_0 = 1$ . Inserting this in (3) and equating coefficients of like powers of  $x$  to zero, we obtain the recurrence relations

$$8c_1 + (4a - 1) = 0, \quad (4)$$

$$16c_2 + (4a - 9)c_1 = 0, \quad (5)$$

$$2(r+1)c_{r+1} + [a - (r + \frac{1}{2})^2]c_r + k^4 c_{r-2} = 0 \quad (r \geq 2). \quad (6)$$

From (4)–(6) we find the expressions for the  $c$  to be as follows [103]:

$$c_1 = -\frac{(4a-1)}{8}, \quad c_2 = \frac{(4a-1)(4a-3^2)}{2! 8^2}, \quad (7)$$

$$c_3 = -\frac{(4a-1)(4a-3^2)(4a-5^2)}{3! 8^3} - \frac{1}{3!} k^4, \quad (8)$$

$$c_4 = \frac{(4a-1)(4a-3^2)(4a-5^2)(4a-7^2)}{4! 8^4} + \frac{k^4}{2 \cdot 4!} (4a-13), \quad (9)$$

and so on. It should be noted that, (1) the dominant term and the two which follow are independent of  $k$ , (2) the first member of each

$c$  is identical with that in the asymptotic series for  $J_\nu(v)$  when  $a = \nu^2$ , i.e. the degenerate form of the  $c$  when  $k \rightarrow 0$ . If  $x$  remains constant meanwhile, equation (2) reduces to the standard form for the B.F.  $J_\nu(v)$  and  $Y_\nu(v)$ . Frequently the terms involving  $k$  in (8), (9) are small numerically, compared with the earlier terms in the series, and may be neglected, but this point should always be checked. The solution of (2), with  $x = -iv$ , is

$$y = we^{-x} = \frac{e^{iv}}{(-iv)^{\frac{1}{2}}} \sum_{r=0}^{\infty} (-1)^r c_r (-iv)^{-r} = \frac{e^{i(v+\frac{1}{2}\pi)}}{v^{\frac{1}{2}}} \sum_{r=0}^{\infty} c_r (iv)^{-r} \quad (10)$$

$$= \frac{e^{i(v+\frac{1}{2}\pi)}}{v^{\frac{1}{2}}} [(1 - c_2 v^{-2} + c_4 v^{-4} - \dots) - i(c_1 v^{-1} - c_3 v^{-3} + \dots)] \quad (11)$$

$$= \frac{e^{i(v+\frac{1}{2}\pi)}}{v^{\frac{1}{2}}} [P - iQ], \quad (12)$$

$$\text{where} \quad P = 1 - c_2 v^{-2} + c_4 v^{-4} - \dots \quad (13)$$

$$\text{and} \quad Q = c_1 v^{-1} - c_3 v^{-3} + c_5 v^{-5} - \dots \quad (14)$$

The real and imaginary parts of (12) are linearly independent solutions of (1), so we have the two solutions

$$y_1(z) = v^{-\frac{1}{2}} [P \cos(v + \frac{1}{4}\pi) + Q \sin(v + \frac{1}{4}\pi)] \quad (15)$$

$$\text{and} \quad y_2(z) = v^{-\frac{1}{2}} [P \sin(v + \frac{1}{4}\pi) - Q \cos(v + \frac{1}{4}\pi)]. \quad (16)$$

When  $z \rightarrow +\infty$ , we may write

$$y_1(z) \sim v^{-\frac{1}{2}} \cos(v + \frac{1}{4}\pi) \quad (17)$$

$$\text{and} \quad y_2(z) \sim v^{-\frac{1}{2}} \sin(v + \frac{1}{4}\pi), \quad (18)$$

these being the dominant terms in the asymptotic expansions (15), (16) respectively.

### 11.21. Asymptotic expansions for $Ce_m$ , $Se_m$ , $Fey_m$ , $Gey_m$ , $q > 0$ .

If (18) § 11.20 is multiplied by  $p_{2n}(2/\pi)^{\frac{1}{2}}$ , we obtain (2) § 11.10, the dominant term in the asymptotic formula for  $Ce_{2n}(z, q)$ . Hence using (16) § 11.20 we infer that

$$Ce_{2n}(z, q) \sim p_{2n}(2/\pi v)^{\frac{1}{2}} [P_{2n}^{(a)} \sin(v + \frac{1}{4}\pi) - Q_{2n}^{(a)} \cos(v + \frac{1}{4}\pi)] \quad (a_{2n}). \quad (1)$$

The subscript  $2n$  and the superscript  $(a)$  signify that  $a_{2n}$  is to be used for  $a$  in the formulae for the  $c$  in (7)–(9) § 11.20.

If (17) § 11.20 is multiplied by  $-p_{2n}(2/\pi)^{\frac{1}{2}}$ , we obtain (9) § 11.10, the dominant term in the asymptotic formula for  $Fey_{2n}(z, q)$ . Hence using (15) § 11.20 we infer that

$$Fey_{2n}(z, q) \sim -p_{2n}(2/\pi v)^{\frac{1}{2}} [P_{2n}^{(a)} \cos(v + \frac{1}{4}\pi) + Q_{2n}^{(a)} \sin(v + \frac{1}{4}\pi)] \quad (a_{2n}). \quad (2)$$

Writing

$$R_{2n}^{(a)} = \left(\frac{2}{\pi v}\right)^{\frac{1}{2}} [P_{2n}^{(a)} \sin(v + \frac{1}{4}\pi) - Q_{2n}^{(a)} \cos(v + \frac{1}{4}\pi)] \quad (a_{2n}), \quad (3)$$

$$S_{2n}^{(a)} = \left(\frac{2}{\pi v}\right)^{\frac{1}{2}} [P_{2n}^{(a)} \cos(v + \frac{1}{4}\pi) + Q_{2n}^{(a)} \sin(v + \frac{1}{4}\pi)] \quad (a_{2n}), \quad (4)$$

and proceeding as shown above, we arrive at the following:

$$\text{Ce}_{2n+1}(z, q) \sim -p_{2n+1} S_{2n+1}^{(a)} \quad (a_{2n+1}), \quad (5)$$

$$\text{Se}_{2n+1}(z, q) \sim -s_{2n+1} S_{2n+1}^{(b)} \quad (b_{2n+1}), \quad (6)$$

$$\text{Se}_{2n+2}(z, q) \sim s_{2n+2} R_{2n+2}^{(b)} \quad (b_{2n+2}), \quad (7)$$

$$\text{Fey}_{2n+1}(z, q) \sim -p_{2n+1} R_{2n+1}^{(a)} \quad (a_{2n+1}), \quad (8)$$

$$\text{Gey}_{2n+1}(z, q) \sim -s_{2n+1} R_{2n+1}^{(b)} \quad (b_{2n+1}), \quad (9)$$

$$\text{Gey}_{2n+2}(z, q) \sim -s_{2n+2} S_{2n+2}^{(b)} \quad (b_{2n+2}). \quad (10)$$

In the series for  $R_m^{(a),(b)}$ ,  $S_m^{(a),(b)}$  the  $c$  in § 11.20 are obtained using the characteristic numbers given at the r.h.s.

The asymptotic expansions for  $\text{Me}_m^{(1),(2)}(z, q)$ ,  $\text{Ne}_m^{(1),(2)}(z, q)$  may be written down immediately by aid of (1), (2) § 13.40 and the appropriate formulae above. Then by means of § 13.41 the asymptotic expansions for  $\text{Fek}_m(z, q)$ ,  $\text{Gek}_m(z, q)$  may be derived. The phase range in the above formulae is  $-\frac{1}{2}\pi < \text{phase } z < \frac{1}{2}\pi$ .

**11.22. Degeneration of expansions in § 11.21 to those for  $J_m(k_1 r)$ ,  $Y_m(k_1 r)$ .** By Appendix I when  $z \rightarrow +\infty$ ,  $k \rightarrow 0$ ,  $a \rightarrow 4n^2$ , then  $ke^z \rightarrow k_1 r$  and

$$\text{Ce}_{2n}(z, q) \rightarrow p'_{2n} J_{2n}(k_1 r). \quad (1)$$

As  $k \rightarrow 0$ , the series  $P_{2n}^{(a)}$ ,  $Q_{2n}^{(a)}$  degenerate to those in the asymptotic expansion of  $J_{2n}(k_1 r)$ , excluding the factors

$$(2/\pi k_1 r)^{\frac{1}{2}} \frac{\cos(k_1 r - \frac{1}{4}\pi - n\pi)}{\sin}$$

[see reference 202, p. 158]. In a similar way, under the above conditions, the asymptotic expansion of  $\text{Fey}_{2n}(z, q)$  degenerates to  $p'_{2n}$  times that of  $Y_{2n}(k_1 r)$ , and so on.

**11.23. Accurate asymptotic expansions for  $q < 0$ .** These are derived by applying the definitions at (1), (4),... § 8.30 to the expansions for  $q > 0$  in § 11.21. Thus from (1) § 8.30 and (1) § 11.21 we obtain

$$\text{Ce}_{2n}(z, -q) \sim \frac{p'_{2n}}{(2\pi v)^{\frac{1}{2}}} \left[ e^v \sum_{r=0}^{\infty} c_r v^{-r} - i e^{-v} \sum_{r=0}^{\infty} (-1)^r c_r v^{-r} \right] \quad (a_{2n}), \quad (1)$$

the  $c$  being those in § 11.20 with  $a = a_{2n}$ ,  $c_0 = 1$ . Since

$$\text{Ce}_{2n}(z, -q) = \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} \cosh 2rz,$$

it is a real function if  $z$  is real. The imaginary part of (1) must *then* be omitted. This remark applies also to (3)–(5) below. The phase-range for formulae in this section is  $-\frac{1}{2}\pi < \text{phase } z < \frac{1}{2}\pi$ . Under the conditions stated in § 11.22

$$\text{Ce}_{2n}(z, -q) \rightarrow p'_{2n} I_{2n}(k_1 r), \quad (2)$$

and the part in [ ] in (1) degenerates to the series which occur in the asymptotic formula for  $I_{2n}(k_1 r)$ .

For the other functions we obtain

$$\text{Ce}_{2n+1}(z, -q) \sim \frac{s'_{2n+1}}{(2\pi v)^{\frac{1}{2}}} \left[ e^v \sum_{r=0}^{\infty} c_r v^{-r} + i e^{-v} \sum_{r=0}^{\infty} (-1)^r c_r v^{-r} \right] \quad (b_{2n+1}), \quad (3)$$

the  $c$  being those in § 11.20 with  $a = b_{2n+1}$ .

$$\text{Se}_{2n+1}(z, -q) \sim \frac{p'_{2n+1}}{(2\pi v)^{\frac{1}{2}}} [\text{as at (3) but } a = a_{2n+1}] \quad (a_{2n+1}), \quad (4)$$

$$\text{Se}_{2n+2}(z, -q) \sim \frac{s'_{2n+2}}{(2\pi v)^{\frac{1}{2}}} [\text{as at (1) but } a = b_{2n+2}] \quad (b_{2n+2}). \quad (5)$$

Each of the four functions above tends to  $+\infty$  monotonically as  $z \rightarrow +\infty$ .

$$\text{Fey}_{2n}(z, -q) \sim \frac{p'_{2n}}{(2\pi v)^{\frac{1}{2}}} i [\text{as at (3) but } a = a_{2n}] \quad (a_{2n}), \quad (6)$$

$$\text{Fey}_{2n+1}(z, -q) \sim \frac{s'_{2n+1}}{(2\pi v)^{\frac{1}{2}}} i [\text{as at (1) but } a = b_{2n+1}] \quad (b_{2n+1}), \quad (7)$$

$$\text{Gey}_{2n+1}(z, -q) \sim \frac{p'_{2n+1}}{(2\pi v)^{\frac{1}{2}}} i [\text{as at (1) but } a = a_{2n+1}] \quad (a_{2n+1}), \quad (8)$$

$$\text{Gey}_{2n+2}(z, -q) \sim \frac{s'_{2n+2}}{(2\pi v)^{\frac{1}{2}}} i [\text{as at (3) but } a = b_{2n+2}] \quad (b_{2n+2}). \quad (9)$$

Each of the four functions in (6)–(9) tends to  $+i\infty$  monotonically as  $z \rightarrow +\infty$ .

Applying the relationship (10) § 8.30 to the expansions (1), (6) above, yields

$$\text{Fek}_{2n}(z, -q) \sim \frac{p'_{2n}}{(2\pi v)^{\frac{1}{2}}} e^{-v} \sum_{r=0}^{\infty} (-1)^r c_r v^{-r} \quad (a_{2n}), \quad (10)$$

the  $c$  being those in § 11.20 with  $a = a_{2n}$ ,  $c_0 = 1$ . The formulae for  $\text{Fek}_{2n+1}(z, -q)$ ,  $\text{Gek}_{2n+1}(z, -q)$ ,  $\text{Gek}_{2n+2}(z, -q)$  are obtained from

(10) on replacing  $p'_{2n}$  by  $s'_{2n+1}$ ,  $p'_{2n+1}$ ,  $s'_{2n+2}$ , respectively, and using the  $c$  corresponding to the characteristic numbers  $b_{2n+1}$ ,  $a_{2n+1}$ ,  $b_{2n+2}$ . These functions tend to zero monotonically as  $z \rightarrow +\infty$ .

When the conditions in § 11.22 are satisfied,

$$\frac{1}{(2\pi v)^{\frac{1}{2}}} e^{-v} \sum_{r=0}^{\infty} (-1)^r c_r v^{-r} \rightarrow \frac{1}{\pi} K_{2n}(k_1 r), \quad (11)$$

i.e.  $1/\pi$  times the asymptotic expansion of the  $K$ -Bessel function. The degenerate forms of the four asymptotic expansions above are then constant multiples of each other. Formulae for  $\text{Me}_m^{(1),(2)}(z, -q)$ ,  $\text{Ne}^{(1),(2)}(z, -q)$  may be derived from (10) and kindred formulae, by aid of the relationships in § 13.41.

**11.30. Alternative asymptotic expansions in  $z$ , with argument  $2k \cosh z$ .** Previously the argument has been  $v = ke^z$ , but it may sometimes be expedient to use  $u = 2k \cosh z$ , so we shall develop the appropriate asymptotic series.

The functions  $\text{Ce}_m(z, q)$ ,  $\text{Fey}_m(z, q)$ ,  $q > 0$ . Let  $x = -2ik \cosh z$  in (1) § 11.20 and we get

$$(x^2 + 4k^2)y'' + xy' - (x^2 + p^2)y = 0, \quad (1)$$

where  $p^2 = (a + 2k^2)$ . Writing  $y = we^{-x}$  in (1) transforms it to

$$(x^2 + 4k^2)w'' - (2x^2 - x + 8k^2)w' - (x - p_1^2)w = 0, \quad (2)$$

with  $p_1^2 = (2k^2 - a)$ . As in § 11.20 we now assume that

$$w = \sum_{r=0}^{\infty} (-1)^r d_r x^{-r-\frac{1}{2}}, \quad (3)$$

with  $d_0 = 1$ .

Inserting (3) in (2) and equating coefficients of like powers of  $x$  to zero, we obtain the relations [52]

$$d_1 = \frac{1}{2}(p_1^2 + \frac{1}{4}), \quad (4)$$

$$d_2 = \frac{1}{8}(p_1^2 + \frac{1}{4})(p_1^2 + \frac{9}{4}) - k^2, \quad (5)$$

$$2(r+1)d_{r+1} = [p_1^2 + \frac{1}{4}(2r+1)^2]d_r - 4k^2(2r-1)d_{r-1} + k^2(2r-1)(2r-3)d_{r-2} \quad (r \geq 2). \quad (6)$$

By expressing (4), (5) in a slightly different way, they are readily compared with (7) § 11.20. Thus

$$d_1 = -\frac{(4a - 1^2 - 8k^2)}{8} = -\frac{(4a - 1^2)}{8} + k^2, \quad (7)$$

$$d_2 = \frac{(4a - 1^2)(4a - 3^2)}{2! 8^2} - \frac{1}{2}k^2(a + \frac{3}{4} - k^2). \quad (8)$$

Writing  $T = 1 - d_2 u^{-2} + d_4 u^{-4} - \dots,$  (9)

$U = d_1 u^{-1} - d_3 u^{-3} + d_5 u^{-5} - \dots,$  (10)

by aid of §§ 11.10, 11.21 we obtain

$$Ce_{2n}(z, q) \sim p_{2n} \left( \frac{2}{\pi u} \right)^{\frac{1}{2}} [T_{2n}^{(a)} \sin(u + \frac{1}{4}\pi) - U_{2n}^{(a)} \cos(u + \frac{1}{4}\pi)] (a_{2n}), \quad (11)$$

$$Ce_{2n+1}(z, q) \sim -p_{2n+1} \left( \frac{2}{\pi u} \right)^{\frac{1}{2}} [T_{2n+1}^{(a)} \cos(u + \frac{1}{4}\pi) + U_{2n+1}^{(a)} \sin(u + \frac{1}{4}\pi)] (a_{2n+1}), \quad (12)$$

$$Fey_{2n}(z, q) \sim -p_{2n} \left( \frac{2}{\pi u} \right)^{\frac{1}{2}} [\text{as at (12) but with } 2n \text{ for } 2n+1] (a_{2n}), \quad (13)$$

$$Fey_{2n+1}(z, q) \sim -p_{2n+1} \left( \frac{2}{\pi u} \right)^{\frac{1}{2}} [\text{as at (11) but with } 2n+1 \text{ for } 2n] (a_{2n+1}). \quad (14)$$

The phase range of (11)–(14) is  $-\frac{1}{2}\pi < \text{phase } z < \frac{1}{2}\pi$ .

When  $k \rightarrow 0$ , the parts  $(2/\pi u)^{\frac{1}{2}}[\quad]$  in (11)–(14) degenerate to the asymptotic expansions for the Bessel functions  $J_{2n}(u)$ ,  $J_{2n+1}(u)$ ,  $Y_{2n}(u)$ ,  $Y_{2n+1}(u)$ , respectively (see § 11.22).

**11.31. Formulae for  $q < 0$ .** To obtain these use definitions (1), (11), etc. § 8.30 in (11)–(14) § 11.30. Then  $u = 2k \cosh z$  becomes  $2ik \sinh z$ , and the required expansions are found if in (1), (3), (6), (7) § 11.23 we write  $2k \sinh z$  for  $v$  and  $d_r$  for  $c_r$ .

**11.32. The functions  $Se_m(z, q)$ ,  $Gey_m(z, q)$ ,  $q > 0$ .** First we derive the differential equation for  $\chi(z) = y(z)/\sinh z$  by writing

$$y(z) = \chi(z) \sinh z$$

in (1) § 11.20.

It transforms to

$$\frac{d^2 \chi}{dz^2} + 2 \coth z \frac{d\chi}{dz} + (4k^2 \cosh^2 z + 1 - p^2) \chi = 0, \quad (1)$$

where  $p^2 = a + 2k^2$ . The solution of (1) is, therefore,  $y/\sinh z$ , where  $y$  may be  $Se_m(z, q)$ ,  $Gey_m(z, q)$ . Now write  $x = -2ik \cosh z$  and (1) becomes [52]

$$(x^2 + 4k^2) \frac{d^2 \chi}{dx^2} + 3x \frac{d\chi}{dx} - (p^2 + x^2 - 1) \chi = 0. \quad (2)$$

If in (2) we substitute  $\chi = we^{-x}$ , we obtain

$$(x^2 + 4k^2)w'' - (2x^2 - 3x + 8k^2)w' - (3x - p_1^2 - 1)w = 0, \quad (3)$$

with  $p_1^2 = (2k^2 - a)$ .

To solve (3) assume that

$$w = \sum_{r=0}^{\infty} (-1)^r e_r x^{-r-\frac{1}{2}}. \quad (4)$$

Inserting (4) into (3) and equating coefficients of like powers of  $x$  to zero, we obtain [52]

$$e_1 = \frac{1}{2}(p_1^2 + \frac{1}{4}), \quad (5)$$

$$e_2 = \frac{1}{8}(p_1^2 + \frac{1}{4})(p_1^2 + \frac{9}{4}) - 3k^2, \quad (6)$$

$$2(r+1)e_{r+1} = [(p_1^2 + 1) + \frac{1}{4}(2r+3)(2r-1)]e_r - 4k^2(2r+1)e_{r-1} + k^2(4r^2-1)e_{r-2} \quad (r \geq 2). \quad (7)$$

Then using the procedure in § 11.20 with  $u = 2k \cosh z$ ,

$$V = 1 - e_2 u^{-2} + e_4 u^{-4} - \dots \quad (8)$$

$$\text{and} \quad W = e_1 u^{-1} - e_3 u^{-3} + e_5 u^{-5} - \dots, \quad (9)$$

we obtain the asymptotic expansions

$$\begin{aligned} \text{Se}_{2n+1}(z, q) &\sim -s_{2n+1} \tanh z \left(\frac{2}{\pi u}\right)^{\frac{1}{2}} \times \\ &\times [V_{2n+1}^{(b)} \cos(u + \frac{1}{4}\pi) + W_{2n+1}^{(b)} \sin(u + \frac{1}{4}\pi)] \quad (b_{2n+1}), \end{aligned} \quad (10)$$

$$\begin{aligned} \text{Se}_{2n+2}(z, q) &\sim s_{2n+2} \tanh z \left(\frac{2}{\pi u}\right)^{\frac{1}{2}} \times \\ &\times [V_{2n+2}^{(b)} \sin(u + \frac{1}{4}\pi) - W_{2n+2}^{(b)} \cos(u + \frac{1}{4}\pi)] \quad (b_{2n+2}), \end{aligned} \quad (11)$$

$$\begin{aligned} \text{Gey}_{2n+1}(z, q) &\sim -s_{2n+1} \tanh z \left(\frac{2}{\pi u}\right)^{\frac{1}{2}} \times \\ &\times [\text{as at (11) but } 2n+1 \text{ for } 2n+2] \quad (b_{2n+1}), \end{aligned} \quad (12)$$

$$\begin{aligned} \text{Gey}_{2n+2}(z, q) &\sim -s_{2n+2} \tanh z \left(\frac{2}{\pi u}\right)^{\frac{1}{2}} \times \\ &\times [\text{as at (10) but } 2n+2 \text{ for } 2n+1] \quad (b_{2n+2}). \end{aligned} \quad (13)$$

The phase range of (10)–(13) is  $-\frac{1}{2}\pi < \text{phase } z < \frac{1}{2}\pi$ .

When  $k \rightarrow 0$ , the parts  $(2/\pi u)^{\frac{1}{2}}[\quad]$  in (10)–(13) degenerate to the asymptotic expansions for the Bessel functions  $J_{2n+1}(u)$ ,  $J_{2n+2}(u)$ ,  $Y_{2n+1}(u)$ ,  $Y_{2n+2}(u)$ , respectively (see § 11.22).

**11.33. Formulae for  $q < 0$ .** Write  $2k \sinh z$  for  $v$ ,  $e_r$  for  $c_r$  in (4), (5), (8), (9) § 11.23 and multiply by  $\coth z$ . The expansions so obtained are identical with those found by applying the definitions (21), (31), (24), (34) § 8.30, respectively, to (10)–(13) § 11.32.

**11.34. Formulae for  $\text{Fek}_m(z, -q)$ ,  $\text{Gek}_m(z, -q)$ .** These may be obtained from the asymptotic expansions for  $\text{Ce}_m(z, -q)$ ,  $\text{Fey}_m(z, -q)$ ,  $\text{Se}_m(z, -q)$ ,  $\text{Gey}_m(z, -q)$  and application of formulae (10), (20), (30), (40) § 8.30.

**11.40. Asymptotic formulae for  $\text{ce}_m(z, q)$ ,  $\text{se}_m(z, q)$  when  $q$  is large and positive [52].** From (12) § 12.21 we see that when  $q$  is very large and positive,  $a \sim -2q + O(q^{\frac{1}{2}})$ , so we shall assume that

$$a = -2q + \alpha q^{\frac{1}{2}} + \alpha_0 + \alpha_1 q^{-\frac{1}{2}} + \alpha_2 q^{-1} + \alpha_3 q^{-\frac{3}{2}} + \dots, \quad (1)$$

where  $\alpha, \alpha_0, \alpha_1, \dots$  are constants dependent upon the function and its order. Putting this series for  $a$  in the standard Mathieu equation for  $\text{ce}_m, \text{se}_m$  gives

$$y'' - (4q \cos^2 z)y + (\alpha q^{\frac{1}{2}} + \alpha_0 + \alpha_1 q^{-\frac{1}{2}} + \alpha_2 q^{-1} + \dots)y = 0. \quad (2)$$

To solve this equation we assume that [73, 101]

$$y = e^{q^{\frac{1}{2}}\chi(z)}\zeta(z)[1 + q^{-\frac{1}{2}}f_1(z) + q^{-1}f_2(z) + \dots]. \quad (3)$$

Substituting (3) into (2) and equating coefficients of  $q, q^{\frac{1}{2}}, q^0, q^{-\frac{1}{2}}, q^{-1}$  to zero yields the equations

$$[\chi']^2 = 4 \cos^2 z, \quad (4)$$

$$2\chi'\zeta' + (\alpha + \chi'')\zeta = 0, \quad (5)$$

$$\zeta'' + (\alpha_0 + 2\chi'f_1')\zeta = 0, \quad (6)$$

$$f_1\zeta'' + 2f_1'\zeta' + (f_1'' + 2\chi'f_2' + \alpha_0 f_1 + \alpha_1)\zeta = 0, \quad (7)$$

$$f_2\zeta'' + 2f_2'\zeta' + (f_2'' + 2\chi'f_3' + \alpha_0 f_2 + \alpha_1 f_1 + \alpha_2)\zeta = 0. \quad (8)$$

Solving (4), (5) we obtain

$$\left. \begin{aligned} \chi &= \pm 2 \sin z + \text{a constant} \\ \text{and } \zeta &= \text{a constant}/(\cos z)^{\frac{1}{2}}\{\tan(\tfrac{1}{2}z + \tfrac{1}{4}\pi)\}^{\pm \alpha/4}. \end{aligned} \right\} \quad (9)$$

Inserting (9) into (3) leads to the first approximations:

$$y_1 = e^{2k \sin z}/(\cos z)^{\frac{1}{2}}\{\tan(\tfrac{1}{2}z + \tfrac{1}{4}\pi)\}^{\alpha/4} \quad (10)$$

$$\text{and } y_2 = e^{-2k \sin z}\{\tan(\tfrac{1}{2}z + \tfrac{1}{4}\pi)\}^{\alpha/4}/(\cos z)^{\frac{1}{2}}. \quad (11)$$

These are formal approximate solutions of  $y'' + (a - 2q \cos 2z)y = 0$ , when  $q$  is large and positive.

A first approximation to (1) is

$$a + 2q \simeq \alpha q^{\frac{1}{2}}, \quad (12)$$

$$\text{and from § 12.30 } a + 2q \sim 2(2p+1)q^{\frac{1}{2}}, \quad (13)$$

where  $p = 0$  for  $\text{ce}_0, \text{se}_1$ ;  $p = m$  for  $\text{ce}_m, \text{se}_{m+1}$ . Thus we take

$$\alpha = 2(2p+1). \quad (14)$$

If in addition we use the formulae

$$[\tan(\tfrac{1}{2}z + \tfrac{1}{4}\pi)]^{-\frac{1}{2}} = 2^{\frac{1}{2}} \cos(\tfrac{1}{2}z + \tfrac{1}{4}\pi) / \cos^{\frac{1}{2}} z, \quad (15)$$

$$[\tan(\tfrac{1}{2}z + \tfrac{1}{4}\pi)]^{\frac{1}{2}} = 2^{\frac{1}{2}} \sin(\tfrac{1}{2}z + \tfrac{1}{4}\pi) / \cos^{\frac{1}{2}} z, \quad (16)$$

(10), (11) may be expressed in the form

$$y_1 = 2^{p+\frac{1}{2}} e^{2k \sin z} [\cos(\tfrac{1}{2}z + \tfrac{1}{4}\pi)]^{2p+1} / (\cos z)^{p+1} \quad (17)$$

and 
$$y_2 = 2^{p+\frac{1}{2}} e^{-2k \sin z} [\sin(\tfrac{1}{2}z + \tfrac{1}{4}\pi)]^{2p+1} / (\cos z)^{p+1}. \quad (18)$$

Writing  $-z$  for  $z$  in (18) gives (17), and vice versa.

**11.41. Construction of asymptotic formulae for  $ce_m$ ,  $se_m$ ,  $q$  large and positive [52].** First we remark that (17) § 11.40 has poles at  $z = \dots -\frac{5}{2}\pi, -\frac{1}{2}\pi, \frac{3}{2}\pi, \frac{7}{2}\pi, \dots$ , and in general at  $z = (4r+3)\frac{1}{2}\pi$ ,  $r = -\infty$  to  $+\infty$ . Also (18) § 11.40 has poles at  $z = \frac{1}{2}\pi(2r+1)$ . Since  $ce_m$ ,  $se_m$  are bounded functions, the variable  $z$  must be restricted to exclude the singularities of (17), (18) § 11.40.

Secondly, using the two latter formulae, the solutions of Mathieu's equation may be expressed by  $y = \epsilon y_1 \pm \theta y_2$ , where  $\epsilon, \theta$  are appropriate constants: for  $ce_0$ ,  $se_1$ ,  $p = 0$ , so bearing in mind the interchangeability of (17), (18) § 11.40, we choose  $\epsilon = \theta = C_0 2^{-\frac{1}{2}}$ . Thus we obtain

$$C_0 [e^{2k \sin z} \cos(\tfrac{1}{2}z + \tfrac{1}{4}\pi) \pm e^{-2k \sin z} \sin(\tfrac{1}{2}z + \tfrac{1}{4}\pi)] / \cos z, \quad (1)$$

these being valid in  $-\frac{1}{2}\pi < z < \frac{1}{2}\pi$  and  $\frac{1}{2}\pi < z < \frac{3}{2}\pi$ , thereby avoiding the singularities mentioned above. We have now to discriminate between these solutions to ascertain which represents  $ce_0$  and which  $se_1$ . With the upper/lower sign (1) is even/odd in  $-\frac{1}{2}\pi < z < \frac{1}{2}\pi$ , and with the lower/upper sign it is even/odd in  $\frac{1}{2}\pi < z < \frac{3}{2}\pi$ . Hence we have deduced that when  $q > 0$  is large enough,

$$\begin{matrix} ce_0 \\ se_1 \end{matrix} (z, q) \sim C_0 [e^{2k \sin z} \cos(\tfrac{1}{2}z + \tfrac{1}{4}\pi) + e^{-2k \sin z} \sin(\tfrac{1}{2}z + \tfrac{1}{4}\pi)] / \cos z, \quad (2)$$

the open interval  $-\frac{1}{2}\pi < z < \frac{1}{2}\pi$  pertaining to  $ce_0$  and  $\frac{1}{2}\pi < z < \frac{3}{2}\pi$  to  $se_1$ . Also

$$\begin{matrix} ce_0 \\ se_1 \end{matrix} (z, q) \sim C_0 [e^{2k \sin z} \cos(\tfrac{1}{2}z + \tfrac{1}{4}\pi) - e^{-2k \sin z} \sin(\tfrac{1}{2}z + \tfrac{1}{4}\pi)] / \cos z, \quad (3)$$

the open interval  $\frac{1}{2}\pi < z < \frac{3}{2}\pi$  for  $ce_0$  and  $-\frac{1}{2}\pi < z < \frac{1}{2}\pi$  for  $se_1$ .

An argument similar to that above enables the following to be derived:

$$\begin{aligned} & \left. \begin{array}{l} \text{ce}_m \\ \text{se}_{m+1} \end{array} (z, q) \text{ in } -\frac{1}{2}\pi < z < \frac{1}{2}\pi \right\} \\ & \sim \frac{C_m}{S_{m+1}} \{e^{2k \sin z} [\cos(\frac{1}{2}z + \frac{1}{4}\pi)]^{2m+1} \pm e^{-2k \sin z} [\sin(\frac{1}{2}z + \frac{1}{4}\pi)]^{2m+1}\} / \cos^{m+1} z. \end{aligned} \quad (4)$$

For the interval  $\frac{1}{2}\pi < z < \frac{3}{2}\pi$ , alter the centre signs to  $\mp$ . The constants  $C, S$  are determined in § 11.42.

*q large and negative.* The formulae for this case may be derived from (2)–(4) by applying the relationships in § 2.18 and altering the range of  $z$  accordingly.

**11.42. Formulae for  $\text{Ce}_m(z, q)$ ,  $\text{Se}_{m+1}(z, q)$ ,  $q$  large and positive.** If the method given in §§ 11.40, 11.41 is applied to (1) § 2.30, use being made of the fact that  $\text{Ce}$  is even and  $\text{Se}$  odd, the results obtained are those in § 11.41 with  $zi$  written for  $z$ . Thus

$$\begin{aligned} \text{Ce}_m(z, q) \sim 2^{\frac{1}{2}} C_m [e^{2ik \sinh z} (\cosh \frac{1}{2}z - i \sinh \frac{1}{2}z)^{2m+1} + \\ + e^{-2ik \sinh z} (\cosh \frac{1}{2}z + i \sinh \frac{1}{2}z)^{2m+1}] / (2 \cosh z)^{m+1}. \end{aligned} \quad (1)$$

Putting  $a = \cosh \frac{1}{2}z$ ,  $b = \sinh \frac{1}{2}z$ ,  $\theta = \tan^{-1}(b/a)$ , (1) becomes

$$\text{Ce}_m(z, q) \sim \frac{[\frac{1}{2}(a^2 + b^2)]^{m+1} C_m}{(\cosh z)^{m+1}} \{e^{i[2k \sinh z - (2m+1)\theta]} + e^{-i[2k \sinh z - (2m+1)\theta]}\}, \quad (2)$$

$$= \frac{C_m}{2^{m-\frac{1}{2}} \cosh^{\frac{1}{2}} z} \cos[2k \sinh z - (2m+1)\tan^{-1}(\tanh \frac{1}{2}z)]. \quad (3)$$

In the same way we find that

$$\text{Se}_{m+1}(z, q) \sim \frac{S_{m+1}}{2^{m-\frac{1}{2}} \cosh^{\frac{1}{2}} z} \sin[2k \sinh z - (2m+1)\tan^{-1}(\tanh \frac{1}{2}z)]. \quad (4)$$

The phase range of (3), (4) is  $-\frac{1}{2}\pi < \text{phase } z < \frac{1}{2}\pi$ . For  $z$  imaginary, formulae in §§ 11.41, 11.43 may be used.

When  $z \rightarrow +\infty$ ,  $\cosh z \rightarrow v/2k$ ,  $2k \sinh z \rightarrow v$ ,  $\tanh \frac{1}{2}z \rightarrow 1$ , so that (3) degenerates to

$$\text{Ce}_m(z, q) \sim C_m \frac{(\pi k)^{\frac{1}{2}}}{2^{m-\frac{1}{2}}} \left(\frac{2}{\pi v}\right)^{\frac{1}{2}} \cos(v - \frac{1}{4}\pi - \frac{1}{2}m\pi). \quad (5)$$

Thus with  $m = 2n$ ,  $2n+1$  we get

$$\text{Ce}_{2n}(z, q) \sim C_{2n} (-1)^n \frac{(\pi k)^{\frac{1}{2}}}{2^{2n-\frac{1}{2}}} \left(\frac{2}{\pi v}\right)^{\frac{1}{2}} \sin(v + \frac{1}{4}\pi), \quad (6)$$

$$\text{Ce}_{2n+1}(z, q) \sim C_{2n+1} (-1)^{n+1} \frac{(\pi k)^{\frac{1}{2}}}{2^{2n+\frac{1}{2}}} \left(\frac{2}{\pi v}\right)^{\frac{1}{2}} \cos(v + \frac{1}{4}\pi). \quad (7)$$

From (4) we have

$$\text{Se}_{m+1}(z, q) \sim S_{m+1} \frac{(\pi k)^{\frac{1}{2}}}{2^{m-\frac{1}{2}}} \left(\frac{2}{\pi v}\right)^{\frac{1}{2}} \sin(v - \frac{1}{4}\pi - \frac{1}{2}m\pi), \quad (8)$$

so 
$$\text{Se}_{2n+1}(z, q) \sim S_{2n+1}(-1)^{n+1} \frac{(\pi k)^{\frac{1}{2}}}{2^{2n-\frac{1}{2}}} \left(\frac{2}{\pi v}\right)^{\frac{1}{2}} \cos(v + \frac{1}{4}\pi) \quad (9)$$

and 
$$\text{Se}_{2n+2}(z, q) \sim S_{2n+2}(-1)^{n+1} \frac{(\pi k)^{\frac{1}{2}}}{2^{2n+\frac{1}{2}}} \left(\frac{2}{\pi v}\right)^{\frac{1}{2}} \sin(v + \frac{1}{4}\pi). \quad (10)$$

The expressions for the  $C$  and  $S$  may now be written down on comparison with (2), (4), (5), (7) § 11.10, since as  $z \rightarrow +\infty$  the corresponding formulae tend to equality. Thus we get [52]

$$C_{2n} = (-1)^n 2^{2n-\frac{1}{2}} \text{ce}_{2n}(0) \text{ce}_{2n}(\frac{1}{2}\pi) / A_0^{(2n)}(\pi k)^{\frac{1}{2}}, \quad (11)$$

$$C_{2n+1} = (-1)^{n+1} 2^{2n+\frac{1}{2}} \text{ce}'_{2n+1}(0) \text{ce}'_{2n+1}(\frac{1}{2}\pi) / k A_1^{(2n+1)}(\pi k)^{\frac{1}{2}}, \quad (12)$$

$$S_{2n+1} = (-1)^n 2^{2n-\frac{1}{2}} \text{se}'_{2n+1}(0) \text{se}_{2n+1}(\frac{1}{2}\pi) / k B_1^{(2n+1)}(\pi k)^{\frac{1}{2}}, \quad (13)$$

$$S_{2n+2} = (-1)^{n+1} 2^{2n+\frac{1}{2}} \text{se}'_{2n+2}(0) \text{se}'_{2n+2}(\frac{1}{2}\pi) / k^2 B_2^{(2n+2)}(\pi k)^{\frac{1}{2}}. \quad (14)$$

$q$  large and negative. The formulae for this case may be derived by applying (1), (11); (21), (31) § 8.30 to (3); (4) above, and taking the real part, when  $z$  is real.

**11.43. Higher approximations [52].** (6) § 11.40 may be expressed in the form

$$f'_1 = -[\alpha_0 + \zeta''/\zeta]/2\chi'. \quad (1)$$

Substituting from (9) § 11.40 into (1) and taking  $m_1 = (2m+1)$  gives

$$f_1(z) = \mp \left(\frac{1}{32}\right) \left[ \{ (m_1^2 + 3) \sin z \mp 4m_1 / \cos^2 z \} + (m_1^2 + 1 + 8\alpha_0) \log_e \tan(\frac{1}{2}z + \frac{1}{4}\pi) \right]. \quad (2)$$

The additive constant of integration has been omitted, since it does not affect the ultimate result. Then the second approximations are

$$\left. \begin{array}{l} \text{ce}_m \\ \text{se}_{m+1} \end{array} (z, q) \text{ in } -\frac{1}{2}\pi < z < \frac{1}{2}\pi \right\} \sim K_m [y_1(1 - {}_2f_1 q^{-1}) \pm y_2(1 + {}_2f_1 q^{-1})] / 2^{m+\frac{1}{2}}. \quad (3)$$

For the interval  $\frac{1}{2}\pi < z < \frac{3}{2}\pi$ , alter the centre signs in (3) to  $\mp$ .  $y_1, y_2$  are, respectively, (17), (18) § 11.40, while  ${}_2f_1, {}_2f_1$  represent  $f_1$  in (2) with two negative or two positive signs. Since  $\text{ce}_m, \text{se}_{m+1}$  are periodic, (3) must not alter, save in sign, when  $-z$  is written for  $z$ . Hence the logarithmic term must vanish, so

$$\alpha_0 = -(m_1^2 + 1)/8 = -(2m^2 + 2m + 1)/4. \quad (4)$$

Thus the second approximations for  $q$  large and positive are

$$\left. \begin{aligned} & \frac{ce_m}{se_{m+1}}(z, q) \text{ in } -\frac{1}{2}\pi < z < \frac{1}{2}\pi \Big\} \\ & \sim \frac{C_m}{S_{m+1}} \left\{ e^{2k \sin z} [\cos(\frac{1}{2}z + \frac{1}{4}\pi)]^{2m+1} \times \right. \\ & \quad \times [1 + \{(2m+1) - (m^2 + m + 1)\sin z\} / 8k \cos^2 z] \pm \\ & \quad \pm e^{-2k \sin z} [\sin(\frac{1}{2}z + \frac{1}{4}\pi)]^{2m+1} \times \\ & \quad \times [1 + \{(2m+1) + (m^2 + m + 1)\sin z\} / 8k \cos^2 z] \Big\} / \cos^{m+1} z. \quad (5) \end{aligned}$$

For the interval  $\frac{1}{2}\pi < z < \frac{3}{2}\pi$ , alter the centre signs to  $\mp$ . Remembering that the log term in (2) is zero, we see that  $f_1(z)$  has singularities at  $z = \frac{1}{2}\pi(2r+1)$ ,  $r$  any integer, and these are common to (5). Thus the formula is invalid in the neighbourhood of any of these points, so (5) must be restricted to the condition that  $k \cos^2 z$  is large enough.

**11.44. Asymptotic expansion for  $a$  [52, 92, 93].** If in § 11.43 the analysis is extended up to  $f_5$ , and at each stage the logarithmic term is made to vanish by equating its coefficient to zero, the values of the  $\alpha$  in (1) § 11.40 are obtained in terms of  $m_1$  and  $q$ . Then we get the following asymptotic expansion:

$$\begin{aligned} a \sim & -2q + 2m_1 q^{\frac{1}{2}} - (m_1^2 + 1)2^{-3} - (m_1^3 + 3m_1)q^{-\frac{1}{2}}2^{-7} - \\ & - (5m_1^4 + 34m_1^2 + 9)q^{-1}2^{-12} - (33m_1^5 + 410m_1^3 + 405m_1)q^{-\frac{3}{2}}2^{-17} - \\ & - (63m_1^6 + 1260m_1^4 + 2943m_1^2 + 486)q^{-2}2^{-20} - \\ & - (527m_1^7 + 15617m_1^5 + 69001m_1^3 + 41607m_1)q^{-\frac{5}{2}}2^{-25} - \dots, \quad (1) \end{aligned}$$

with  $m_1 = (2p+1)$ .  $p = 0$  gives  $a_0, b_1$ ;  $p = 1$  gives  $a_1, b_2$ ; and in general  $p = m$  gives  $a_m, b_{m+1}$ . Since all the characteristic curves  $a_{m+\beta}$  lying between  $a_m, b_{m+1}$  are mutually asymptotic when  $q$  is large enough, (1) gives  $a_{m+\beta}$  for  $p = m$ . This will be clear from Figs. 8, 11. In references [92, 93] formula (1) is derived by a procedure different from that outlined above. Both methods involve some very heavy algebra.

When  $q \rightarrow +\infty$ , (1) may be written

$$a \sim -2q + 2(2p+1)q^{\frac{1}{2}}, \quad (2)$$

so the form in § 12.30 is reproduced.

For  $p$  moderate, (1) gives accurate results for comparatively small values of  $q$ . For an assigned  $q$ , the accuracy decreases with increase in  $p$ . Thus to maintain accuracy to a definite number of decimal

places (or units in the  $s$ th significant figure, whichever is preferred)  $q$  must increase with increase in  $p$ . We may say that (1) gives adequate accuracy, provided  $p^2/q$  is not too large. To illustrate the order of accuracy attained for various  $q$ , Table 20 is appended. When  $q > 40$ , formula (1) with  $p = 0, 1$  gives  $a$  correct to the fifth decimal place at least. The accurate values were obtained from reference [52]. Additional information regarding the accuracy of (1) is given on p. 299 reference [93].

TABLE 20. *Data illustrating accuracy of formula (1)*

Values of $q$	$-a_0, -b_1$ from (1)	Accurate values		$-a_1, -b_2$ from (1)	Accurate values	
		$-a_0$	$-b_1$		$-a_1$	$-b_2$
8	10.60604	10.60672	10.60536	0.41144	0.43596	0.38936
16	24.25868	24.25868	24.25864	9.33456	9.35268	9.33412
40	67.64216	67.64216	67.64216	43.35228	43.35228	43.35228

In reference [56] asymptotic formulae are deduced for the difference between two characteristic numbers in a stable region of the  $(a, q)$  plane. There are also asymptotic formulae for  $a$  when the curves  $a_m, b_m$  are approached from an unstable region.

## XII

### ZEROS OF THE MATHIEU AND MODIFIED MATHIEU FUNCTIONS OF INTEGRAL ORDER

**12.10. Real zeros of  $ce_m(z, q)$ ,  $se_m(z, q)$ .** If  $q$  is fixed and  $m \geq 1$ , these functions vanish for certain real values of  $z$ . Consider the case  $q = 0$  when the functions reduce to  $\cos mz$ ,  $\sin mz$ , respectively. In the interval  $0 \leq z < \pi$ , the graphs of  $\cos mz$ ,  $\sin mz$  cross the  $z$ -axis  $m$  times, so each function has  $m$  real zeros in this interval. The case  $m = 3$  is illustrated for  $\cos 3z$  in Fig. 18A, there being three zeros in  $0 \leq z < \pi$ . We shall now demonstrate that the number of zeros of  $ce_3(z, q)$  in  $q \geq 0$  remains constant [87].

Let  $q$  be increased from zero, and suppose that a fourth zero appeared. Its genesis would entail the curve of Fig. 18A bending towards the  $z$ -axis as shown by the broken line. From the theory of equations, the existence of a minimum value above the  $z$ -axis would entail the occurrence of two conjugate complex zeros of the type  $z_1 = \alpha + i\beta$ ,  $z_2 = \alpha - i\beta$ . Further increase in  $q$  would be accompanied by the minimum approaching and ultimately being tangential to the  $z$ -axis, thereby introducing a double zero, i.e.  $z = \alpha$  bis (Fig. 18B). For a greater  $q$  the minimum would occur below the axis, thereby entailing two different simple real zeros (Fig. 18C).

If  $z = \alpha$  were a double zero, we could write

$$ce_3(z, q) = (z - \alpha)^2 f(z) = y(z), \quad \text{say.} \quad (1)$$

Then 
$$y'(z) = 2(z - \alpha)f(z) + (z - \alpha)^2 f'(z), \quad (2)$$

so 
$$y'(\alpha) = 0. \quad (3)$$

Now  $y'' + (a - 2q \cos 2z)y = 0$ , and  $y(\alpha) = 0$ , by hypothesis, so  $y''(\alpha) = 0$ . Hence  $y(\alpha) = y'(\alpha) = y''(\alpha) = 0$ , so  $y(z)$  must be a null function, i.e.  $y(z) \equiv 0$ . But  $ce_3(z, q)$  is not a null function, so a double zero cannot occur. A similar argument may be used to show that the number of zeros cannot decrease. It follows that the number of zeros of  $ce_3(z, q)$  in  $0 \leq z < \pi$  is independent of  $q$  in  $q \geq 0$ . In general a discussion on the above basis leads to the conclusion that  $ce_m$ ,  $se_m$  have  $m$  simple zeros in  $0 \leq z < \pi$ .  $se_m$  has a simple zero at the origin, so it has  $(m - 1)$  zeros in  $0 < z < \pi$ . When  $q = 0$  the zeros are equally spaced, i.e. for the circular functions, but, as shown later, they tend to cluster about  $z = \frac{1}{2}\pi$  as  $q \rightarrow +\infty$ , excepting that

of  $se_m$  at the origin. This discussion shows that as the number of zeros in a given interval is independent of  $q$ , the graphs of  $ce_m$ ,  $se_m$  are distorted versions of those of  $\cos mz$ ,  $\sin mz$  (see Figs. 1-4).

FIG. 18. Illustrating that the number of zeros of a Mathieu function ( $ce$ ,  $se$ ) in a given interval is independent of  $q$ .

**12.20. An inequality for  $a$ ,  $q$ .** We obtain this by aid of Sturm's first comparison theorem which is used for comparing Mathieu's equation with two forms derived therefrom. *First* we remark that integral-order solutions have  $rm$  zeros in the interval  $0 \leq z < r\pi$ ,  $r$  being a positive integer  $> 0$ , e.g.  $ce_2$ ,  $se_3$  have 6, 9 zeros, respectively, in  $0 \leq z < 3\pi$ . *Secondly*, the first maximum of  $(a - 2q \cos 2z)$  occurs when  $z = \frac{1}{2}\pi$  and has the value  $(a + 2q)$ , so we consider the equation

$$y'' + (a + 2q)y = 0. \quad (1)$$

Its formal solutions are  $\cos z(a + 2q)^{\frac{1}{2}}$ ,  $\sin z(a + 2q)^{\frac{1}{2}}$ , and in the interval  $0 \leq z < r\pi$  both of these functions will have at least  $rm$  zeros, provided that

$$(a + 2q)^{\frac{1}{2}} > \left(m - \frac{1}{2r}\right). \quad (2)$$

By Sturm's first comparison theorem the solutions of Mathieu's equation cannot have more zeros in  $0 \leq z < r\pi$  than those in each solution of (1). Hence by (2), if  $ce_m$ ,  $se_m$  each have  $rm$  zeros, it follows that

$$a > \left(m - \frac{1}{2r}\right)^2 - 2q. \quad (3)$$

But  $r$  is arbitrary, so we can make it tend to  $+\infty$ , thereby obtaining the inequality

$$a \geq m^2 - 2q, \quad (4)$$

$q \geq 0$ , the equality sign being for  $q = 0$ .

*Thirdly*, the first minimum of  $(a - 2q \cos 2z)$  occurs when  $z = 0$  and has the value  $(a - 2q)$ . Proceeding as before, we consider the comparison equation

$$y'' + (a - 2q)y = 0, \quad (5)$$

whose formal solutions are  $\cos z(a - 2q)^{\frac{1}{2}}$ ,  $\sin z(a - 2q)^{\frac{1}{2}}$ . In the interval  $0 \leq z < r\pi$ , the number of zeros will not exceed  $rm$ , provided that

$$(a - 2q)^{\frac{1}{2}} < \left(m + \frac{1}{2r}\right). \quad (6)$$

By the comparison theorem the solutions  $ce_m$ ,  $se_m$  each have as many zeros as (but no more than) the solutions of (5) in  $0 \leq z < r\pi$ . Hence

$$(a - 2q) < \left(m + \frac{1}{2r}\right)^2 \quad (7)$$

or

$$a < \left(m + \frac{1}{2r}\right)^2 + 2q. \quad (8)$$

As before, let  $r \rightarrow +\infty$ , and we obtain the inequality

$$a \leq m^2 + 2q, \quad (9)$$

$q \geq 0$ . Combining the inequalities (4), (9) we find that the characteristic numbers for  $ce_m$ ,  $se_m$  satisfy

$$m^2 - 2q \leq a \leq m^2 + 2q, \quad (10)$$

for  $q \geq 0$ , the equality signs pertaining to  $q = 0$ . If  $q < 0$ , we have

$$m^2 - 2q \geq a \geq m^2 + 2q. \quad (11)$$

The analysis herein is based upon reference [87].

**12.21. Form of  $a$  when  $q$  is large.** Here and in the succeeding section it is expedient to use the equation

$$y'' + (a + 2q \cos 2z)y = 0, \quad (1)$$

where  $q > 0$ . From the expansion of  $\cos 2z$  we get the inequality

$$1 - 2z^2 \leq \cos 2z \leq 1 - 2z^2 + 2z^4/3. \quad (2)$$

If in (1) we replace  $\cos 2z$  by the first and third members of (2), we obtain the two comparison equations [91]

$$y'' + (a + 2q - 4qz^2)y = 0 \quad (3)$$

and

$$y'' + (a + 2q - 4qz^2 + \frac{2}{3}qz^4)y = 0. \quad (4)$$

Then by Sturm's first comparison theorem the odd or even solution of (1) has at least as many zeros, in a finite interval, as that of (3), but no more than that of (4). Writing  $z = x/2q^{\frac{1}{2}}$  in (3), (4) yields

$$\frac{d^2y}{dx^2} + \left[ \left( \frac{a+2q}{4q^{\frac{1}{2}}} \right) - \frac{1}{4}x^2 \right] y = 0 \quad (5)$$

and 
$$\frac{d^2y}{dx^2} + \left[ \left( \frac{a+2q}{4q^{\frac{1}{2}}} \right) - \frac{1}{4}x^2 + \frac{x^4}{48q^{\frac{1}{2}}} \right] y = 0. \quad (6)$$

Now the interval of  $z$  to be considered is  $0 \leq z < \pi$ , and since the corresponding range of  $x$  is  $0 \leq x < 2q^{\frac{1}{2}}\pi$ ,  $x$  can be made as large as we please by suitable choice of  $q$ .

Substituting  $l + \frac{1}{2}$  for  $(a+2q)/4q^{\frac{1}{2}}$  in (5) leads to the equation for the parabolic cylinder functions  $D_l(x)$ , i.e.

$$\frac{d^2y}{dx^2} + \left[ \left( l + \frac{1}{2} \right) - \frac{1}{4}x^2 \right] y = 0. \quad (7)$$

Using the notation of (5), it is known [140] that with  $s$  a positive integer, if

$$2s - \frac{1}{2} < \frac{a+2q}{4q^{\frac{1}{2}}} \leq 2s + \frac{3}{2}, \quad (8)$$

the odd solutions of (7) have  $s$  zeros in  $0 < x < +\infty$ , while if

$$2s - \frac{3}{2} < \frac{a+2q}{4q^{\frac{1}{2}}} \leq 2s + \frac{1}{2}, \quad (9)$$

its even solutions have  $s$  zeros in the same interval. Thus for *any* solution of (1) having a finite number of zeros in  $0 \leq z < \pi$ —and this includes periodic and non-periodic classes of solution—it follows that, as  $q \rightarrow +\infty$ ,

$$\frac{a+2q}{4q^{\frac{1}{2}}} = O(1), \quad (10)$$

i.e. it is bounded. It can also be shown that as  $q \rightarrow -\infty$ ,

$$\frac{a-2q}{4|q|^{\frac{1}{2}}} = O(1). \quad (11)$$

Finally, therefore, we obtain the form of  $a$  for  $|q|$  large, namely [91],

$$a = -2|q| + O|q|^{\frac{1}{2}}. \quad (12)$$

**12.22. Distribution of zeros as  $q \rightarrow \infty$  [91].** When  $q \gg x$  in (5), (6) § 12.21 the term in  $x^4$  in the latter may be ignored. Then the two equations are the same, so their respective solutions have an equal number of zeros in a given interval of  $x$ . Now  $z = x/2q^{\frac{1}{2}}$ , so when

$x$  is finite and  $q$  large enough, the solutions of (3), (4) § 12.21 have an equal number of zeros in a given interval. Also the solutions of (3) § 12.21 are non-alternating† if -

$$(a + 2q - 4qz^2) < 0,$$

$$\text{i.e. if} \quad z^2 > (a + 2q)/4q. \quad (1)$$

But from (12) § 12.21, with  $q > 0$  in (1) § 12.21,

$$a = -2q + O(q^{\frac{1}{2}}),$$

so (1) takes the form

$$z^2 > O(q^{\frac{1}{2}})/4q = \lambda^2 q^{-\frac{1}{2}}, \quad (2)$$

$\lambda$  being bounded and positive. Thus in the small interval

$$-\lambda q^{-\frac{1}{2}} < z < \lambda q^{-\frac{1}{2}}, \quad a + 2q - 4qz^2 > 0,$$

so both solutions of (3) § 12.21 are alternating functions.‡ Moreover, they have the same number of zeros in the above interval. Hence, as  $q \rightarrow +\infty$ , any solution of (1) § 12.21 has a finite number of zeros in the interval  $(-\lambda q^{-\frac{1}{2}}, \lambda q^{-\frac{1}{2}})$ . Since  $a = -2q + O(q^{\frac{1}{2}})$ , we get

$$a + 2q \cos 2z = 2q(\cos 2z - 1) + O(q^{\frac{1}{2}}), \quad (3)$$

and in the two intervals  $-\pi + \lambda q^{-\frac{1}{2}} < z < -\lambda q^{-\frac{1}{2}}$ ,  $\lambda q^{-\frac{1}{2}} < z < \pi - \lambda q^{-\frac{1}{2}}$ , neither of which includes the origin, (3) is negative. It follows that the solutions in these intervals do not alternate, and no more than one zero can occur in each. The above argument rests upon the hypothesis that  $q$  is large. Accordingly as  $q \rightarrow +\infty$  the interval  $(-\lambda q^{-\frac{1}{2}}, \lambda q^{-\frac{1}{2}}) \rightarrow 0$ , and the zeros of (1) § 12.21 in the interval  $-\frac{1}{2}\pi \leq z < \frac{1}{2}\pi$  congregate or condense on each side of the origin.

To obtain the result of letting  $q \rightarrow +\infty$  for  $\text{ce}_m(z, q)$ ,  $\text{se}_m(z, q)$ , we remark that  $y'' + (a + 2q \cos 2z)y = 0$  takes the canonical form  $y'' + (a - 2q \cos 2z)y = 0$  if  $(\frac{1}{2}\pi + z)$  be written for  $z$ . Doing this with the above interval, we conclude that as  $q \rightarrow +\infty$  the zeros of  $\text{ce}_m(z, q)$ ,  $\text{se}_m(z, q)$  in  $0 \leq z < \pi$  condense about  $\frac{1}{2}\pi$ , with the exception of one, namely, the zero of  $\text{se}_m(z, q)$  at the origin. The interval of condensation is  $(\frac{1}{2}\pi - \lambda q^{-\frac{1}{2}}, \frac{1}{2}\pi + \lambda q^{-\frac{1}{2}})$ . The condensation phenomenon is illustrated by the curves in Figs. 19 A, B, plotted from data in reference [96]. They are asymptotic to the line  $\theta = 90^\circ = \frac{1}{2}\pi^c$ . The function  $\text{ce}_0(z, q)$  has double zeros at  $z = 0, \pi, 2\pi, \dots$  as  $q \rightarrow +\infty$ , i.e. the graph is tangential to the  $z$ -axis (see Fig. 3,  $\text{ce}_0(z, 8)$ ). It may be remarked that in  $0 < z < \frac{1}{2}\pi$ ,  $\text{ce}_{2n}(z, q)$ ,  $\text{ce}_{2n+1}(z, q)$ ,  $\text{se}_{2n+1}(z, q)$ ,  $\text{se}_{2n+2}(z, q)$  each

† Oscillatory but devoid of real zeros, i.e.  $f(z) \neq 0$ .

‡ Oscillatory but having real zeros.

have  $n$  simple zeros. For this reason  $se_{2n+2}(z, q)$  is used in preference to  $se_{2n}(z, q)$  which has only  $(n-1)$  zeros in the interval.

FIG. 19. Illustrating condensation of zeros at  $\frac{1}{4}\pi$ : (A) for  $ce_2(z, q)$ , (B)  $ce_5(z, q)$ ,  $se_6(z, q)$  as  $q \rightarrow +\infty$ . The curves are asymptotic to  $\theta = \frac{1}{4}\pi$ .  $ce_s, se_s$  each have two zeros in  $0 < z < \frac{1}{4}\pi$  (see Figs. 1, 4).

**12.30. Approximate asymptotic formulae for  $a$  [91].** To obtain these we have to determine a value for  $O(q^{\frac{1}{4}})$  in (12) § 12.21. Consider  $ce_{2n}(z, -q)$ ,  $ce_{2n+1}(z, -q)$ , the even solutions of integral order of  $y'' + (a + 2q \cos 2z)y = 0$ . If  $q > 0$  is large enough, by (9) § 12.21 we may write

$$\frac{a + 2q}{4q^{\frac{1}{4}}} \sim 2s + \frac{1}{2}, \quad (1)$$

the asymptotic sign referring to  $q$ . Transposing (1) and writing  $n$  for  $s$  gives the desired asymptotic formulae, namely,

$$a_{2n}(-q) \sim -2q + (8n + 2)q^{\frac{1}{4}}, \quad (2)$$

$$a_{2n+1}(-q) \sim -2q + (8n + 2)q^{\frac{1}{4}}. \quad (3)$$

If  $q > 0$  is large enough,  $\text{se}_{2n+1}(z, -q)$ ,  $\text{se}_{2n+2}(z, -q)$  each have  $(2n+1)$  zeros in the neighbourhood of the origin, the additional zero of  $\text{se}_{2n+2}$  occurring at  $z = \frac{1}{2}\pi$ . Since  $\text{se}_m(z, -q)$  is odd in  $z$ , by (8) § 12.21 we get

$$\frac{a+2q}{4q^{\frac{1}{2}}} \sim 2s + \frac{3}{2}. \quad (4)$$

This leads to the asymptotic formulae

$$b_{2n+1}(-q) \sim -2q + (8n+6)q^{\frac{1}{2}}, \quad (5)$$

$$b_{2n+2}(-q) \sim -2q + (8n+6)q^{\frac{1}{2}}. \quad (6)$$

Formulae (2), (3), (5), (6) apply to the equation

$$y'' + (a - 2q \cos 2z)y = 0$$

when  $q < 0$ . For  $q$  positive it can be deduced that

$$a_{2n}(q) \sim -2q + (8n+2)q^{\frac{1}{2}}, \quad (7)$$

$$a_{2n+1}(q) \sim -2q + (8n+6)q^{\frac{1}{2}}, \quad (8)$$

$$b_{2n+1}(q) \sim -2q + (8n+2)q^{\frac{1}{2}}, \quad (9)$$

$$b_{2n+2}(q) \sim -2q + (8n+6)q^{\frac{1}{2}}. \quad (10)$$

From the preceding formulae we have the relationships, asymptotic in  $q$  (see Fig. 8),

$$a_{2n}(-q) \sim a_{2n+1}(-q), \quad b_{2n+1}(-q) \sim b_{2n+2}(-q); \quad (11)$$

$$a_{2n}(q) \sim b_{2n+1}(q), \quad a_{2n+1}(q) \sim b_{2n+2}(q),$$

or  $a_m(q) \sim b_{m+1}(q); \quad (12)$

$$\begin{matrix} a_{2n} & (-q) \sim a_{2n} & (q), & b_{2n+1} & (-q) \sim a_{2n+1} & (q). \end{matrix} \quad (13)$$

$\begin{matrix} 2n+1 \\ b_{2n+1} \end{matrix}$ 
 $\begin{matrix} 2n+2 \\ b_{2n+2} \end{matrix}$

In the above formulae  $n$  is assumed to be finite.

**12.31. Accuracy of formulae in § 12.30.** This is illustrated for several cases by the data in Table 21.

TABLE 21

Values of $q$	$-a_0(q) \sim -b_1(q)$		$-a_2(q) \sim -b_3(q)$	
	Value from (7) § 12.30	Accurate value	Value from (7) § 12.30	Accurate value
80	142.12...	142.3671...	70.60...	73.9437...
160	294.71...	294.9453...	193.51...	196.8521...
1600	3120.00	3120.2508...	2800.00	2803.2779...

For  $n = 0$  in (7), (9) § 12.30, i.e. for  $\text{ce}_0(z, q)$ ,  $\text{se}_1(z, q)$ , the discrepancy occurs in the first decimal place, whereas with  $n = 1$ , i.e.  $\text{ce}_2(z, q)$ ,

$se_3(z, q)$ , there is a difference of 3 in each of the digits. Thus for an assigned  $n$  the accuracy increases with increase in  $q$ , but for a given  $q$  it decreases with increase in  $n$ . The 'accurate' values were obtained from ref. [52], p. 325.

**12.40. Zeros of  $Ce_m(z, q)$ ,  $Se_m(z, q)$ ,  $Fey_m(z, q)$ ,  $Gey_m(z, q)$ ,  $z$  large and positive.** Reference to the approximate asymptotic formulae in § 11.10 shows that for any  $k > 0$ , each of these functions has an infinity of zeros. As  $z$  increases, the graphs of the functions oscillate about the  $z$ -axis with steadily decreasing amplitude. The zeros of  $Ce_{2n}(z, q)$ ,  $Se_{2n+2}(z, q)$ ,  $Fey_{2n+1}(z, q)$ ,  $Gey_{2n+1}(z, q)$  occur approximately when  $\sin(v + \frac{1}{4}\pi)$  vanishes. Thus we have

$$v + \frac{1}{4}\pi \simeq r\pi \quad \text{or} \quad ke^z \simeq (r - \frac{1}{4})\pi, \quad (1)$$

$$\text{so} \quad z_r \simeq \log_e[(4r-1)\pi/4k]. \quad (2)$$

Now  $v \gg 1$ , so by (1)  $r \gg 1$  but integral. From (2) it follows that, to the order of approximation contemplated, the zeros in  $z$  are independent of the order of the function.

By § 11.10 the zeros of  $Ce_{2n+1}(z, q)$ ,  $Se_{2n+1}(z, q)$ ,  $Fey_{2n}(z, q)$ ,  $Gey_{2n+2}(z, q)$  occur approximately when  $\cos(v + \frac{1}{4}\pi)$  vanishes. Thus

$$z_r \simeq \log_e[(4r+1)\pi/4k]. \quad (3)$$

*Parametric zeros,  $z$  large and positive.* These are the values of  $q$  for which, with  $z$  assigned, the function vanishes. From (1) we get

$$q_r = k_r^2 \simeq (4r-1)^2 \pi^2 e^{-2z}/16, \quad (4)$$

which gives the parametric zeros of the four functions prior to (1). From (3)

$$q_r = k_r^2 \simeq (4r+1)^2 \pi^2 e^{-2z}/16, \quad (5)$$

which gives the parametric zeros of the four functions just above (3). These formulae are independent of the order of the function. As  $z \rightarrow +\infty$ , the interval between successive zeros tends to vanish, so they condense in the neighbourhood of  $q = +0$ .

**12.41. More accurate formulae for parametric zeros of  $Ce_m(z, q)$ ,  $Se_m(z, q)$ .** These may be derived from (3), (4) § 11.42. From the former we get for  $Ce_{2n}(z, q)$

$$2k \sinh z \simeq (2r+1)\pi/2 + (4n+1)\tan^{-1}(\tanh \frac{1}{2}z), \quad (1)$$

provided  $k$  is large enough. In problems on elliptical membranes and wave guides,  $\cosh z_0 = e^{-1}$  at the bounding ellipse. Thus

$\sinh z_0 = e^{-1}(1-e^2)^{\frac{1}{2}}$ ,  $\tanh \frac{1}{2}z_0 = [(1-e)/(1+e)]^{\frac{1}{2}}$ . Substituting these in (1) leads to

$$\text{Ce}_{2n}(z, q)$$

$$k_r^2 \simeq \{(r + \frac{1}{2})\pi + (4n+1)\tan^{-1}[(1-e)/(1+e)]^{\frac{1}{2}}\}^2 e^2 / 4(1-e^2). \quad (2)$$

For  $\text{Ce}_{2n+1}(z, q)$  write  $(4n+3)$  for  $(4n+1)$  in (2). Similarly (4) § 11.42 leads to

$$\text{Se}_{2n+1}(z, q)$$

$$k_r^2 \simeq \{(r+1)\pi + (4n+1)\tan^{-1}[(1-e)/(1+e)]^{\frac{1}{2}}\}^2 e^2 / 4(1-e^2). \quad (3)$$

For  $\text{Se}_{2n+2}(z, q)$  write  $(4n+3)$  for  $(4n+1)$  in (3).

In these formulae  $r$  takes all integral values  $\geq 1$ . The accuracy improves with increase in  $r$ , also as  $e \rightarrow 1$ , i.e. as the ellipse becomes long and narrow, thereby increasing  $k_r$ .

**12.42. Large zeros of  $\text{Ce}'_m(z, q)$ ,  $\text{Se}'_m(z, q)$ .** By differentiating the formulae in § 11.42 we find that the large zeros of  $\text{Ce}'_m$  are in close agreement with those of  $\text{Se}_{m+1}$ , and a similar remark applies to  $\text{Se}'_m$  and  $\text{Ce}_{m-1}$ . Accordingly the large zeros of  $\text{Ce}'_{2n}(z, q)$  are given by (3) § 12.41, while those of  $\text{Se}'_{2n+1}(z, q)$  are given by (2) § 12.41, and so on.

**12.43. Large zeros of  $J_m(z)$ .** By Appendix I as  $e \rightarrow 0$ , the ellipse tends to a circle,  $\text{Ce}_m(z, q) \rightarrow p'_m J_m(k_1 a)$ ,  $\text{Se}_m(z, q) \rightarrow s'_m J_m(k_1 a)$ : also  $k_1 h = 2k$ ,  $h = ae$ , so  $k_1 a = 2ke^{-1}$ . Thus (2), (3) § 12.41 degenerate to the well-known formulae for the large zeros of the Bessel functions, namely,

$$J_{2n}: \quad k_1 a \simeq (r + \frac{1}{2})\pi + (4n+1)\pi/4 = (r + n + \frac{3}{4})\pi, \quad (1)$$

$$J_{2n+1}: \quad k_1 a \simeq (r+1)\pi + (4n+1)\pi/4 = (r + n + \frac{5}{4})\pi. \quad (2)$$

### XIII

#### SOLUTIONS IN BESSEL FUNCTION PRODUCT SERIES

**13.10. Method of solution [36].** The equation whose solutions we require is

$$y'' - (a - 2q \cosh 2z)y = 0, \quad (1)$$

i.e. the modified Mathieu equation, which may be written in the form

$$y'' + [k^2(e^{2z} + e^{-2z}) - a]y = 0, \quad (2)$$

with  $k^2 = q \neq 0$ . Now

$$w_1 = J_r(ke^{-z}) \text{ satisfies } w_1'' + (k^2e^{-2z} - r^2)w_1 = 0, \quad (3)$$

$$\text{while } w_2 = J_\rho(ke^z) \text{ satisfies } w_2'' + (k^2e^{2z} - \rho^2)w_2 = 0, \quad (4)$$

$r$  integral,  $\rho$  integral or fractional. Multiplying (3) by  $w_2$ , (4) by  $w_1$ , and adding gives

$$w_1''w_2 + w_2''w_1 + [k^2(e^{2z} + e^{-2z}) - r^2 - \rho^2]w_1w_2 = 0, \quad (5)$$

which is equivalent to

$$\frac{d^2}{dz^2}(w_1w_2) + (2k^2 \cosh 2z - r^2 - \rho^2)w_1w_2 = 2w_1'w_2'. \quad (6)$$

Writing  $y = w_1w_2$  and adding  $-ay$  to both sides, (6) becomes

$$\frac{d^2y}{dz^2} + (2k^2 \cosh 2z - a)y = -2k^2 J_r' J_\rho' + (r^2 + \rho^2 - a)J_r J_\rho. \quad (7)$$

By aid of recurrence relations we obtain

$$2J_r' J_\rho' = -\frac{2r\rho}{k^2} J_r J_\rho + J_{r-1} J_{\rho-1} + J_{r+1} J_{\rho+1}. \quad (8)$$

Substituting from (8) into the r.h.s. of (7) yields the equation

$$\frac{d^2y}{dz^2} + (2k^2 \cosh 2z - a)y = [(r+\rho)^2 - a]J_r J_\rho - k^2(J_{r-1} J_{\rho-1} + J_{r+1} J_{\rho+1}). \quad (9)$$

Writing  $\rho = r + \nu$ , assume that

$$y = \sum_{r=-\infty}^{\infty} (-1)^r d_{2r} J_r(ke^{-z}) J_{r+\nu}(ke^z) \quad (10)$$

is a solution of (1). If  $v_1 = ke^{-z}$ ,  $v_2 = ke^z$ , then we must have, by (9),

$$\begin{aligned} & \sum_{r=-\infty}^{\infty} (-1)^r d_{2r} [(2r+\nu)^2 - a] J_r(v_1) J_{r+\nu}(v_2) - \\ & - k^2 \{J_{r-1}(v_1) J_{r+\nu-1}(v_2) + J_{r+1}(v_1) J_{r+\nu+1}(v_2)\} = 0. \end{aligned} \quad (11)$$

In (11) the coefficient of  $J_r(v_1)J_{r+\nu}(v_2)$  will vanish provided

$$d_{2r}[a - (2r + \nu)^2] - q(d_{2r+2} + d_{2r-2}) = 0. \quad (12)$$

Now 
$$\text{Ce}_{2n+\nu}(z, q) = \sum_{r=-\infty}^{\infty} A_{2r}^{(2n+\nu)} \cosh(2r + \nu)z, \quad (13)$$

satisfies (1), and the recurrence formula for the  $A$  is identical in form with (12). Hence for the same  $a, q$ , if  $d_{2r} = K_{2n+\nu} A_{2r}^{(2n+\nu)}$ ,  $K_{2n+\nu}$  being a constant, it follows that when  $k \neq 0$ ,

$$y = K_{2n+\nu} \sum_{r=-\infty}^{\infty} (-1)^r A_{2r}^{(2n+\nu)} J_r(v_1) J_{r+\nu}(v_2) \quad (14)$$

is a solution of (1). Since (1) is unaltered if we change  $z$  to  $-z$ , then

$$y = K_{2n+\nu} \sum_{r=-\infty}^{\infty} (-1)^r A_{2r}^{(2n+\nu)} J_{r+\nu}(v_1) J_r(v_2) \quad (15)$$

is also a solution. Adding and subtracting (14), (15) yields the two series, even and odd in  $z$ ,

$$K_{2n+\nu} \sum_{r=-\infty}^{\infty} (-1)^r A_{2r}^{(2n+\nu)} [J_r(v_1) J_{r+\nu}(v_2) \pm J_{r+\nu}(v_1) J_r(v_2)], \quad (16)$$

both of which satisfy (1). By analysis similar to that in § 13.60, we find that these series are absolutely and uniformly convergent in any closed region of the  $z$ -plane, *including*  $z = 0$ .

**13.11. B.F. product series for  $\text{Ce}_m(z, q)$ ,  $\text{Se}_m(z, q)$ .** Write  $\beta = \nu$ , and apply (2) § 4.711 to (16) § 13.10 as  $\beta \rightarrow 0$ . Then the first series becomes

$$K_{2n} \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} J_r(v_1) J_r(v_2) \quad (a_{2n}), \quad (1)$$

while the second series vanishes. Now (1) represents an even function of  $z$  with period  $\pi i$ , which is a solution of (1) § 13.10 for  $a = a_{2n}$ . Hence we infer that (1) is a constant multiple of  $\text{Ce}_{2n}(z, q)$ , to which (13) § 13.10 also reduces as  $\nu \rightarrow 0$ . We now determine  $K_{2n}$ . As  $z \rightarrow +\infty$ , all terms of (1) are negligible in comparison with the first, and this has the value

$$K_{2n} A_0^{(2n)} (2/\pi) v_2^{-\frac{1}{2}} \sin(v_2 + \frac{1}{4}\pi), \quad (2)$$

when the dominant term of the asymptotic expansion for  $J_0(v_2)$  is used [202, p. 158, no. 13]. By (2) § 11.10, if  $K_{2n} = p_{2n}/A_0^{(2n)}$ , (2) is

the dominant term in the asymptotic expansion of  $Ce_{2n}(z, q)$ . Thus we obtain†

$$Ce_{2n}(z, q) = (p_{2n}/A_0^{(2n)}) \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} J_r(v_1) J_r(v_2). \quad (3)$$

When  $\beta \rightarrow 1$ , by (4) § 4.711, the first member of (16) § 13.10 vanishes, while the second becomes

$$K_{2n+1} \sum_{r=0}^{\infty} (-1)^r B_{2r+1}^{(2n+1)} [J_r(v_1) J_{r+1}(v_2) - J_{r+1}(v_1) J_r(v_2)] \quad (b_{2n+1}). \quad (4)$$

This series, odd in  $z$  with period  $2\pi i$ , is a solution of (1) § 13.10 with  $a = b_{2n+1}$ , so we infer it to be a constant multiple of  $Se_{2n+1}(z, q)$ . Then procedure akin to that above yields

$$\begin{aligned} Se_{2n+1}(z, q) \\ = (s_{2n+1}/B_1^{(2n+1)}) \sum_{r=0}^{\infty} (-1)^r B_{2r+1}^{(2n+1)} [J_r(v_1) J_{r+1}(v_2) - J_{r+1}(v_1) J_r(v_2)]. \end{aligned} \quad (5)$$

Writing  $\nu = \beta + 1$  in (16) § 13.10, letting  $\beta \rightarrow 0$  and 1 in turn, using (6), (8) § 4.711, and following the procedure already set out, leads to

$$\begin{aligned} Ce_{2n+1}(z, q) \\ = (p_{2n+1}/A_1^{(2n+1)}) \sum_{r=0}^{\infty} (-1)^r A_{2r+1}^{(2n+1)} [J_r(v_1) J_{r+1}(v_2) + J_{r+1}(v_1) J_r(v_2)] \quad (a_{2n+1}) \end{aligned} \quad (6)$$

$$\begin{aligned} Se_{2n+2}(z, q) \\ = -(s_{2n+2}/B_2^{(2n+2)}) \sum_{r=0}^{\infty} (-1)^r B_{2r+2}^{(2n+2)} [J_r(v_1) J_{r+2}(v_2) - J_{r+2}(v_1) J_r(v_2)] \quad (b_{2n+2}). \end{aligned} \quad (7)$$

Solutions of the type herein may be derived by means of integral relations, as shown in § 10.34 et seq.

**13.12. Series for  $Ce_{2n+\beta}(z, q)$ ,  $Se_{2n+\beta}(z, q)$ .** If in (16) § 13.10,  $\nu = \beta$ ,  $0 < \beta < 1$ , comparison of the first solution therein with the series for  $Ce_{2n+\beta}(z, q)$  at (13) § 13.10 shows: (a) both are even in  $z$ ; (b) any  $A$  in (16) § 13.10 is the same as the corresponding coefficient in (13) § 13.10; (c) if  $\beta = p/s$ , a rational fraction in its lowest terms, both solutions have period  $2s\pi i$ . (b), (c) apply also to the odd solution in (16) § 13.10 and  $Se_{2n+\beta}(z, q)$  at (12) § 4.71. Further, the solutions at (16) § 13.10 constitute a fundamental system, as also do  $Ce_{2n+\beta}$ ,  $Se_{2n+\beta}$ . Hence we infer that they are constant multiples of each other, so we write

$$Ce_{2n+\beta}(z, q) = \frac{K_{2n+\beta}}{K_{2n+\beta}} \sum_{r=-\infty}^{\infty} (-1)^r A_{2r}^{(2n+\beta)} [J_r(v_1) J_{r+\beta}(v_2) \pm J_{r+\beta}(v_1) J_r(v_2)] \quad (a_{2n+\beta}). \quad (1)$$

† See Appendix I for  $p_{2n}$ .

Let  $z = 0$ , and we get

$$K_{2n+\beta} = ce_{2n+\beta}(0, q) \Big/ 2 \sum_{r=-\infty}^{\infty} (-1)^r A_{2r}^{(2n+\beta)} J_r(k) J_{r+\beta}(k). \quad (2)$$

Differentiating and putting  $z = 0$  gives

$$\bar{K}_{2n+\beta} = se'_{2n+\beta}(0, q) \Big/ 2k \sum_{r=-\infty}^{\infty} (-1)^r A_{2r}^{(2n+\beta)} [J_r(k) J'_{r+\beta}(k) - J_{r+\beta}(k) J'_r(k)]. \quad (3)$$

The series for  $Ce_{2n+1+\beta}$ ,  $Se_{2n+1+\beta}$  are obtained from above by writing  $(1+\beta)$  for  $\beta$ . Analysis similar to that in § 13.60 shows that the series (1) are absolutely and uniformly convergent for  $z$  finite.

**13.20. Second solutions of (1) § 13.10: functions of integral order.**  $Y_p$  and  $J_p$  satisfy the same D.E. and recurrence relations of the same type. Since it is by virtue of these that the B.F. product series satisfy (1) § 13.10, it follows that a second linearly independent solution may be obtained on replacing  $J_m(v_2)$  by  $Y_m(v_2)$  in the first solution in § 13.11. Thus, corresponding to (3) § 13.11, we get

$$\text{Fey}_{2n}(z, q) = (p_{2n}/A_0^{(2n)}) \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} J_r(v_1) Y_r(v_2). \quad (1)$$

This function is non-periodic owing to the term  $\log_e(ke^z)$  in the expansion of  $Y_r(v_2)$  [202, p. 161, no. 61]; for  $\log_e(ke^z) = \log_e k + z$ . Using the said expansion gives

$$\begin{aligned} J_r(ke^{-z}) Y_r(ke^z) &= \frac{2}{\pi} (\gamma + \log \tfrac{1}{2} k) J_r(ke^{-z}) J_r(ke^z) + \\ &+ \frac{2}{\pi} z J_r(ke^{-z}) J_r(ke^z) + \sum \cosh \text{ terms} + \sum \sinh \text{ terms}. \end{aligned} \quad (2)$$

The arguments of the  $\cosh$ ,  $\sinh$  terms are even multiples of  $z$ , and result from the relation  $e^{\pm 2mz} = \cosh 2mz \pm \sinh 2mz$ . Applying (2) to (1) leads to the representation

$$\begin{aligned} \text{Fey}_{2n}(z, q) &= \left[ \frac{2}{\pi} (\gamma + \log \tfrac{1}{2} k) Ce_{2n}(z, q) + (p_{2n}/A_0^{(2n)}) \sum \cosh \text{ terms} \right] + \\ &+ \left[ \frac{2}{\pi} z Ce_{2n}(z, q) + (p_{2n}/A_0^{(2n)}) \sum \sinh \text{ terms} \right] \quad (3) \\ &= \text{even function of } z, \text{ with period } \pi i + \text{odd non-periodic} \\ &\quad \text{function of } z. \end{aligned} \quad (4)$$

In Chapter VII it is shown that if one solution of (1) § 13.10 is even and periodic in  $z$  with period  $\pi i$ , the other is odd in  $z$  but non-periodic. A combination with two *arbitrary* constants constitutes a fundamental system. Accordingly on comparing (3) with the solutions in §§ 2.30,

7.61 we infer that the first  $\sum$  is a multiple of  $\text{Ce}_{2n}(z, q)$ , while the odd function is a multiple of  $\text{Fe}_{2n}(z, q)$ . Thus we may write

$$\text{Fey}_{2n}(z, q) = A \text{Ce}_{2n}(z, q) + B \text{Fe}_{2n}(z, q), \quad (5)$$

where  $A, B$  are *particular* constants. A similar relation pertains to functions of order  $(2n+1)$ : also

$$\text{Gey}_m(z, q) = \bar{A} \text{Se}_m(z, q) + \bar{B} \text{Ge}_m(z, q). \quad (6)$$

It appears, therefore, that  $\text{Fey}_m(z, q)$ ,  $\text{Gey}_m(z, q)$  include the first and second solutions, but none of these functions constitutes a fundamental system in itself. The  $A, B$ , are determined in § 13.21.

Proceeding as heretofore we obtain:

$$\begin{aligned} \text{Fey}_{2n+1}(z, q) &= (p_{2n+1}/A_1^{(2n+1)}) \times \\ &\times \sum_{r=0}^{\infty} (-1)^r A_{2r+1}^{(2n+1)} [J_r(v_1)Y_{r+1}(v_2) + J_{r+1}(v_1)Y_r(v_2)], \end{aligned} \quad (7)$$

$$\begin{aligned} \text{Gey}_{2n+1}(z, q) &= (s_{2n+1}/B_1^{(2n+1)}) \times \\ &\times \sum_{r=0}^{\infty} (-1)^r B_{2r+1}^{(2n+1)} [J_r(v_1)Y_{r+1}(v_2) - J_{r+1}(v_1)Y_r(v_2)], \end{aligned} \quad (8)$$

$$\begin{aligned} \text{Gey}_{2n+2}(z, q) &= -(s_{2n+2}/B_2^{(2n+2)}) \times \\ &\times \sum_{r=0}^{\infty} (-1)^r B_{2r+2}^{(2n+2)} [J_r(v_1)Y_{r+2}(v_2) - J_{r+2}(v_1)Y_r(v_2)]. \end{aligned} \quad (9)$$

Series for  $\text{Fek}_m(z, q)$ ,  $\text{Gek}_m(z, q)$  may be derived from (1), (7)-(9) by aid of (4), (7), (10), (13) § 8.14.

**13.21. Relationships between  $\text{Fey}_m$ ,  $\text{Fe}_m$ ;  $\text{Gey}_m$ ,  $\text{Ge}_m$ .** Writing  $z = 0$  in (5) § 13.20, with  $m$  for  $2n$ , we get

$$A = \text{Fey}_m(0, q)/\text{Ce}_m(0, q) \quad (1)$$

since  $\text{Fe}_m(0, q) = 0$ . Also

$$\text{Fey}'_m = A \text{Ce}'_m + B \text{Fe}'_m; \quad (2)$$

so when  $z = 0$ ,  $\text{Ce}'_m = 0$  and

$$B = \text{Fey}'_m(0, q)/\text{Fe}'_m(0, q). \quad (3)$$

Hence by (1), (3) above, and (5) § 13.20, we find that

$$\text{Fey}_m(z, q) = \frac{\text{Fey}_m(0, q)}{\text{Ce}_m(0, q)} \text{Ce}_m(z, q) + \frac{\text{Fey}'_m(0, q)}{\text{Fe}'_m(0, q)} \text{Fe}_m(z, q). \quad (4)$$

Similarly we obtain

$$\text{Gey}_m(z, q) = \frac{\text{Gey}'_m(0, q)}{\text{Se}'_m(0, q)} \text{Se}_m(z, q) + \frac{\text{Gey}_m(0, q)}{\text{Ge}_m(0, q)} \text{Ge}_m(z, q). \quad (5)$$

See § 13.31 respecting  $\text{Fey}'_m(0, q)$ ,  $\text{Gey}_m(0, q)$ .

By (4) § 8.14 we have

$$\text{Fey}_{2n} = i \text{Ce}_{2n} - 2 \text{Fek}_{2n} \quad (6)$$

$$= A \text{Ce}_{2n} + B \text{Fe}_{2n}. \quad (7)$$

$$\text{Hence } \text{Fek}_{2n}(z, q) = \frac{1}{2}(i - A) \text{Ce}_{2n}(z, q) - \frac{1}{2} B \text{Fe}_{2n}(z, q). \quad (8)$$

$A, B$  being given by (1), (3). It may be remarked that by § 8.14,  $\text{Fek}_{2n}(z, q)$  is complex for  $z$  real. Relations of the type (8) may be found for  $\text{Fek}_{2n+1}, \text{Gek}_m$ .

**13.30. Integral order solutions of  $y'' - (a + 2q \cosh 2z)y = 0$ .** Applying (1), (11), (21), (31) § 8.30 to (3), (5)–(7) § 13.11, each to each, we obtain the first solutions:

$$\begin{aligned} \text{Ce}_{2n}(z, -q) \\ = (p'_{2n}/A_0^{(2n)}) \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} I_r(v_1) I_r(v_2), \end{aligned} \quad (1)$$

$$\begin{aligned} \text{Ce}_{2n+1}(z, -q) \\ = (s'_{2n+1}/B_1^{(2n+1)}) \sum_{r=0}^{\infty} (-1)^r B_{2r+1}^{(2n+1)} [I_r(v_1) I_{r+1}(v_2) + I_{r+1}(v_1) I_r(v_2)], \end{aligned} \quad (2)$$

$$\begin{aligned} \text{Se}_{2n+1}(z, -q) \\ = (p'_{2n+1}/A_1^{(2n+1)}) \sum_{r=0}^{\infty} (-1)^r A_{2r+1}^{(2n+1)} [I_r(v_1) I_{r+1}(v_2) - I_{r+1}(v_1) I_r(v_2)], \end{aligned} \quad (3)$$

$$\begin{aligned} \text{Se}_{2n+2}(z, -q) \\ = (s'_{2n+2}/B_2^{(2n+2)}) \sum_{r=0}^{\infty} (-1)^r B_{2r+2}^{(2n+2)} [I_r(v_1) I_{r+2}(v_2) - I_{r+2}(v_1) I_r(v_2)]. \end{aligned} \quad (4)$$

The second solutions involving the  $K$ -Bessel function may be obtained from the series in §§ 13.20, 13.30 by applying (4), (10); (14), (20); (24), (30); (34), (40) § 8.30 and (2) § 8.14. They are as follow:

$$\begin{aligned} \text{Fek}_{2n}(z, -q) \\ = (p'_{2n}/\pi A_0^{(2n)}) \sum_{r=0}^{\infty} A_{2r}^{(2n)} I_r(v_1) K_r(v_2), \end{aligned} \quad (5)$$

$$\begin{aligned} \text{Fek}_{2n+1}(z, -q) \\ = (s'_{2n+1}/\pi B_1^{(2n+1)}) \sum_{r=0}^{\infty} B_{2r+1}^{(2n+1)} [I_r(v_1) K_{r+1}(v_2) - I_{r+1}(v_1) K_r(v_2)], \end{aligned} \quad (6)$$

$$\begin{aligned} \text{Gek}_{2n+1}(z, -q) \\ = (p'_{2n+1}/\pi A_1^{(2n+1)}) \sum_{r=0}^{\infty} A_{2r+1}^{(2n+1)} [I_r(v_1) K_{r+1}(v_2) + I_{r+1}(v_1) K_r(v_2)], \end{aligned} \quad (7)$$

$$\begin{aligned} \text{Gek}_{2n+2}(z, -q) \\ = (s'_{2n+2}/\pi B_2^{(2n+2)}) \sum_{r=0}^{\infty} B_{2r+2}^{(2n+2)} [I_r(v_1) K_{r+2}(v_2) - I_{r+2}(v_1) K_r(v_2)]. \end{aligned} \quad (8)$$

Absence of  $(-1)^r$  in these series should be noted.

Series for  $\text{Fey}_m(z, -q)$ ,  $\text{Gey}_m(z, -q)$  may be derived from (1)–(8) using (10), (20), (30), (40) § 8.30. Relationships of the type in § 13.21 may be obtained also, e.g.

$$\text{Fek}_{2n}(z, -q) = \frac{\text{Fek}_{2n}(0, -q)}{\text{Ce}_{2n}(0, -q)} \text{Ce}_{2n}(z, -q) + \frac{\text{Fek}'_{2n}(0, -q)}{\text{Fe}'_{2n}(0, -q)} \text{Fe}_{2n}(z, -q). \quad (9)$$

$\text{Fek}'_m(0, -q)$ ,  $\text{Gek}_m(0, -q)$  are given in § 13.31: note that

$$\text{Ce}_{2n}(0, -q) = \text{ce}_{2n}(\tfrac{1}{2}\pi, q).$$

**13.31. Evaluation of  $\text{Fey}'_m(0, q)$ ,  $\text{Gey}_m(0, q)$ ,  $\text{Fek}'_m(0, -q)$ ,  $\text{Gek}_m(0, -q)$ .** These are obtained from the series in §§ 13.20, 13.30, by aid of the following B.F. relations, with argument  $k$ :

$$J_r Y'_r - J'_r Y_r = 2/\pi k \quad (\text{the Wronskian relation}), \quad (1)$$

$$J_r Y'_{r+1} - J'_r Y_{r+1} + J_{r+1} Y'_r - J'_{r+1} Y_r = 2(2r+1)/\pi k^2, \quad (2)$$

$$J_r Y_{r+1} - J_{r+1} Y_r = -2/\pi k, \quad (3)$$

$$J_r Y_{r+2} - J_{r+2} Y_r = -4(r+1)/\pi k^2, \quad (4)$$

$$I_r K'_r - I'_r K_r = -1/k \quad (\text{Wronskian for modified B.F.}), \quad (5)$$

$$I_r K'_{r+1} + I'_{r+1} K_r - I_{r+1} K'_r - I'_r K_{r+1} = -(2r+1)/k^2, \quad (6)$$

$$I_r K_{r+1} + I_{r+1} K_r = 1/k, \quad (7)$$

$$I_r K_{r+2} - I_{r+2} K_r = (2r+2)/k^2. \quad (8)$$

It will be seen that the r.h.s. of (5)–(8) are given by  $-\frac{1}{2}\pi$  times (1)–(4), each to each. For (1), (5) see [202, p. 156, ex. 60, 61]. The remainder may be derived therefrom by aid of recurrence relations.

The results obtained are as follows:

$$\text{Fey}'_{2n}(0, q) = \frac{2p_{2n}}{\pi A_0^{(2n)}} \text{ce}_{2n}(\tfrac{1}{2}\pi, q), \quad (9)$$

$$\text{Fey}'_{2n+1}(0, q) = -\frac{2p_{2n+1} \text{ce}'_{2n+1}(\tfrac{1}{2}\pi, q)}{\pi k A_1^{(2n+1)}}, \quad (10)$$

$$\text{Gey}_{2n+1}(0, q) = -\frac{2s_{2n+1} \text{se}_{2n+1}(\tfrac{1}{2}\pi, q)}{\pi k B_1^{(2n+1)}}, \quad (11)$$

$$\text{Gey}_{2n+2}(0, q) = -\frac{2s_{2n+2} \text{se}'_{2n+2}(\tfrac{1}{2}\pi, q)}{\pi k^2 B_2^{(2n+2)}}, \quad (12)$$

$$\text{Fek}'_{2n}(0, -q) = -\frac{p'_{2n} \text{ce}_{2n}(0, q)}{\pi A_0^{(2n)}}, \quad (13)$$

$$\text{Fek}'_{2n+1}(0, -q) = -\frac{s'_{2n+1} \text{se}'_{2n+1}(0, q)}{\pi k B_1^{(2n+1)}}, \quad (14)$$

$$\text{Gek}_{2n+1}(0, -q) = \frac{p'_{2n+1} \text{ce}_{2n+1}(0, q)}{\pi k A_1^{(2n+1)}}, \quad (15)$$

$$\text{Gek}_{2n+2}(0, -q) = \frac{s'_{2n+2} \text{se}'_{2n+2}(0, q)}{\pi k^2 B_2^{(2n+2)}}. \quad (16)$$

**13.40. Combination solutions.** In problems on wave motion using elliptical coordinates, it is expedient to have solutions akin to the Hankel functions  $H_m^{(1),(2)}(z)$ . The latter are used to represent incoming and outgoing waves in problems pertaining to circular cylinders. Accordingly for wave-motion problems involving elliptical cylinders we shall adopt the following definitions:

$$\text{Me}_m^{(1),(2)}(z, q) = \text{Ce}_m(z, q) \pm i \text{Fey}_m(z, q) \quad (a_m), \quad (1)$$

$$\text{and} \quad \text{Ne}_m^{(1),(2)}(z, q) = \text{Se}_m(z, q) \pm i \text{Gey}_m(z, q) \quad (b_m). \quad (2)$$

Then by aid of §§ 8.10–8.13, 13.11, 13.20 we get

$$\text{Me}_{2n}^{(1),(2)}(z, q) = \frac{\text{ce}_{2n}(\frac{1}{2}\pi, q)}{A_0^{(2n)}} \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} H_{2r}^{(1),(2)}(2k \cosh z) \quad (3)$$

$$= \frac{\text{ce}_{2n}(0, q)}{A_0^{(2n)}} \sum_{r=0}^{\infty} A_{2r}^{(2n)} H_{2r}^{(1),(2)}(2k \sinh z) \quad (4)$$

$$= (p_{2n}/A_0^{(2n)}) \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} J_r(v_1) H_r^{(1),(2)}(v_2). \quad (5)$$

$$\text{Me}_{2n+1}^{(1),(2)}(z, q) = -\frac{\text{ce}'_{2n+1}(\frac{1}{2}\pi, q)}{k A_1^{(2n+1)}} \sum_{r=0}^{\infty} (-1)^r A_{2r+1}^{(2n+1)} H_{2r+1}^{(1),(2)}(2k \cosh z) \quad (6)$$

$$= \frac{\text{ce}'_{2n+1}(0, q)}{k A_1^{(2n+1)}} \coth z \sum_{r=0}^{\infty} (2r+1) A_{2r+1}^{(2n+1)} H_{2r+1}^{(1),(2)}(2k \sinh z) \quad (7)$$

$$= (p_{2n+1}/A_1^{(2n+1)}) \sum_{r=0}^{\infty} (-1)^r A_{2r+1}^{(2n+1)} [J_r(v_1) H_{r+1}^{(1),(2)}(v_2) + J_{r+1}(v_1) H_r^{(1),(2)}(v_2)]. \quad (8)$$

$$\begin{aligned} \text{Ne}_{2n+1}^{(1),(2)}(z, q) &= \frac{\text{se}_{2n+1}(\frac{1}{2}\pi, q)}{k B_1^{(2n+1)}} \tanh z \times \\ &\quad \times \sum_{r=0}^{\infty} (-1)^r (2r+1) B_{2r+1}^{(2n+1)} H_{2r+1}^{(1),(2)}(2k \cosh z) \quad (9) \end{aligned}$$

$$= \frac{\text{se}'_{2n+1}(0, q)}{k B_1^{(2n+1)}} \sum_{r=0}^{\infty} B_{2r+1}^{(2n+1)} H_{2r+1}^{(1),(2)}(2k \sinh z) \quad (10)$$

$$= (s_{2n+1}/B_1^{(2n+1)}) \sum_{r=0}^{\infty} (-1)^r B_{2r+1}^{(2n+1)} [J_r(v_1) H_{r+1}^{(1),(2)}(v_2) - J_{r+1}(v_1) H_r^{(1),(2)}(v_2)]. \quad (11)$$

$$\begin{aligned} \text{Ne}_{2n+2}^{(1),(2)}(z, q) &= -\frac{se'_{2n+2}(\frac{1}{2}\pi, q)}{k^2 B_2^{(2n+2)}} \tanh z \times \\ &\quad \times \sum_{r=0}^{\infty} (-1)^r (2r+2) B_{2r+2}^{(2n+2)} H_{2r+2}^{(1),(2)}(2k \cosh z) \quad (12) \end{aligned}$$

$$\begin{aligned} &= \frac{se'_{2n+2}(0, q)}{k^2 B_2^{(2n+2)}} \coth z \times \\ &\quad \times \sum_{r=0}^{\infty} (2r+2) B_{2r+2}^{(2n+2)} H_{2r+2}^{(1),(2)}(2k \sinh z) \quad (13) \end{aligned}$$

$$\begin{aligned} &= -(s_{2n+2}/B_2^{(2n+2)}) \sum_{r=0}^{\infty} (-1)^r B_{2r+2}^{(2n+2)} [J_r(v_1) H_{r+2}^{(1),(2)}(v_2) - \\ &\quad - J_{r+2}(v_1) H_r^{(1),(2)}(v_2)]. \quad (14) \end{aligned}$$

Series for  $q < 0$ . These may be obtained by aid of the following definitions:

$$\begin{aligned} \text{Me}_{2n}^{(1),(2)}(z, -q) &= (-1)^n \text{Me}_{2n}^{(1),(2)}(\tfrac{1}{2}\pi i + z, q) \\ &= \text{Ce}_{2n}(z, -q) \pm i \text{Fey}_{2n}(z, -q), \quad (15) \end{aligned}$$

$$\begin{aligned} \text{Ne}_{2n+2}^{(1),(2)}(z, -q) &= (-1)^{n+1} \text{Ne}_{2n+2}^{(1),(2)}(\tfrac{1}{2}\pi i + z, q) \\ &= \text{Se}_{2n+2}(z, -q) \pm i \text{Gey}_{2n+2}(z, -q), \quad (16) \end{aligned}$$

$$\begin{aligned} \text{Me}_{2n+1}^{(1),(2)}(z, -q) &= (-1)^{n+1} i \text{Ne}_{2n+1}^{(1),(2)}(\tfrac{1}{2}\pi i + z, q) \\ &= \text{Ce}_{2n+1}(z, -q) \pm i \text{Fey}_{2n+1}(z, -q), \quad (17) \end{aligned}$$

$$\begin{aligned} \text{Ne}_{2n+1}^{(1),(2)}(z, -q) &= (-1)^{n+1} i \text{Me}_{2n+1}^{(1),(2)}(\tfrac{1}{2}\pi i + z, q) \\ &= \text{Se}_{2n+1}(z, -q) \pm i \text{Gey}_{2n+1}(z, -q). \quad (18) \end{aligned}$$

**13.41. Relationship between  $\text{Me}_m^{(1)}$ ,  $\text{Fek}_m$ ;  $\text{Ne}_m^{(1)}$ ,  $\text{Gek}_m$ .** Applying (4), (7), (10), (13) § 8.14, and (10), (20), (30), (40), § 8.30 to (1), (2) § 13.40 leads to

$$\text{Me}_{2n}^{(1)}(z, \pm q) = -2i \text{Fek}_{2n}(z, \pm q), \quad (1)$$

$$\text{Me}_{2n+1}^{(1)}(z, q) = -2 \text{Fek}_{2n+1}(z, q), \quad (2)$$

$$\text{Me}_{2n+1}^{(1)}(z, -q) = 2i \text{Fek}_{2n+1}(z, -q), \quad (3)$$

$$\text{Ne}_{2n+1}^{(1)}(z, q) = -2 \text{Gek}_{2n+1}(z, q), \quad (4)$$

$$\text{Ne}_{2n+1}^{(1)}(z, -q) = 2i \text{Gek}_{2n+1}(z, -q), \quad (5)$$

$$\text{Ne}_{2n+2}^{(1)}(z, \pm q) = -2i \text{Gek}_{2n+2}(z, \pm q). \quad (6)$$

**13.50. Series for**  $\frac{ce}{se_m}(z, q), \frac{ce}{se_{m+\beta}}(z, q)$ . Writing  $-iz$  for  $z$  in (3) § 13.11 gives

$$ce_{2n}(z, q) = (p_{2n}/A_0^{(2n)}) \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} J_r(v'_1) J_r(v'_2), \quad (1)$$

where  $v'_1 = ke^{iz}$ ,  $v'_2 = ke^{-iz}$ . The r.h.s. of (1) is even in  $z$ . If  $z$  is real,  $v'_1$  and  $v'_2$  are conjugate, so the r.h.s. is real, as we should expect. If  $z$  is complex,  $v'_1, v'_2$  are not conjugate and (1) is, therefore, complex.

Writing  $-iz$  for  $z$  in (6) § 13.11 yields

$$ce_{2n+1}(z, q) = (p_{2n+1}/A_1^{(2n+1)}) \times \\ \times \sum_{r=0}^{\infty} (-1)^r A_{2r+1}^{(2n+1)} [J_r(v'_1) J_{r+1}(v'_2) + J_{r+1}(v'_1) J_r(v'_2)], \quad (2)$$

the r.h.s. being even in  $z$ . If  $z$  is real the two product pairs are conjugate, since one is derived from the other by changing the sign of  $i$ . Thus the part in [ ] takes the form

$$(x+iy) + (x-iy) = 2x, \quad (3)$$

a real function expressible in a cosine series, since  $e^{\pm iz} = \cos z \pm i \sin z$ . By virtue of (3), if  $z$  is real,

$$ce_{2n+1}(z, q) = (2p_{2n+1}/A_1^{(2n+1)}) \sum_{r=0}^{\infty} (-1)^r A_{2r+1}^{(2n+1)} \text{Real}[J_r(v'_1) J_{r+1}(v'_2)]. \quad (4)$$

Similarly we obtain

$$se_{2n+1}(z, q) = (s_{2n+1}/i B_1^{(2n+1)}) \times \\ \times \sum_{r=0}^{\infty} (-1)^r B_{2r+1}^{(2n+1)} [J_r(v'_1) J_{r+1}(v'_2) - J_{r+1}(v'_1) J_r(v'_2)], \quad (5)$$

and, if  $z$  is real,

$$se_{2n+1}(z, q) = (2s_{2n+1}/B_1^{(2n+1)}) \times \\ \times \sum_{r=0}^{\infty} (-1)^r B_{2r+1}^{(2n+1)} \text{Imag}[J_r(v'_1) J_{r+1}(v'_2)]; \quad (6)$$

$$se_{2n+2}(z, q) = -(s_{2n+2}/i B_2^{(2n+2)}) \times \\ \times \sum_{r=0}^{\infty} (-1)^r B_{2r+2}^{(2n+2)} [J_r(v'_1) J_{r+2}(v'_2) - J_{r+2}(v'_1) J_r(v'_2)], \quad (7)$$

and, if  $z$  is real,

$$se_{2n+2}(z, q) = -(2s_{2n+2}/B_2^{(2n+2)}) \times \\ \times \sum_{r=0}^{\infty} (-1)^r B_{2r+2}^{(2n+2)} \text{Imag}[J_r(v'_1) J_{r+2}(v'_2)]. \quad (8)$$

Series for  $ce_{m+\beta}(z, q)$ ,  $se_{m+\beta}(z, q)$  may be derived from § 13.12 by the above substitutions.

**13.51. Series for  $\text{ce}_m(z, -q)$ ,  $\text{se}_m(z, -q)$ .** Applying the relationships (2)–(5) § 13.18 to the formulae in § 13.50 yields the results given below.

$$\text{ce}_{2n}(z, -q) = (p'_{2n}/A_0^{(2n)}) \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} I_r(v'_1) I_r(v'_2). \quad (1)$$

This function, as represented by the r.h.s., is even in  $z$ , real or complex with  $z$ .

$$\begin{aligned} \text{ce}_{2n+1}(z, -q) &= -(s'_{2n+1}/B_1^{(2n+1)}) \times \\ &\times \sum_{r=0}^{\infty} (-1)^r B_{2r+1}^{(2n+1)} [I_r(v'_1) I_{r+1}(v'_2) + I_{r+1}(v'_1) I_r(v'_2)], \end{aligned} \quad (2)$$

and, if  $z$  is real,

$$\begin{aligned} \text{ce}_{2n+1}(z, -q) &= -(2s'_{2n+1}/B_1^{(2n+1)}) \times \\ &\times \sum_{r=0}^{\infty} (-1)^r B_{2r+1}^{(2n+1)} \text{Real}[I_r(v'_1) I_{r+1}(v'_2)]; \end{aligned} \quad (3)$$

$$\begin{aligned} \text{se}_{2n+1}(z, -q) &= -(p'_{2n+1}/iA_1^{(2n+1)}) \times \\ &\times \sum_{r=0}^{\infty} (-1)^r A_{2r+1}^{(2n+1)} [I_r(v'_1) I_{r+1}(v'_2) - I_{r+1}(v'_1) I_r(v'_2)], \end{aligned} \quad (4)$$

and, if  $z$  is real,

$$\begin{aligned} \text{se}_{2n+1}(z, -q) &= -(2p'_{2n+1}/A_1^{(2n+1)}) \times \\ &\times \sum_{r=0}^{\infty} (-1)^r A_{2r+1}^{(2n+1)} \text{Imag}[I_r(v'_1) I_{r+1}(v'_2)]; \end{aligned} \quad (5)$$

$$\begin{aligned} \text{se}_{2n+2}(z, -q) &= (s'_{2n+2}/iB_2^{(2n+2)}) \times \\ &\times \sum_{r=0}^{\infty} (-1)^r B_{2r+2}^{(2n+2)} [I_r(v'_1) I_{r+2}(v'_2) - I_{r+2}(v'_1) I_r(v'_2)], \end{aligned} \quad (6)$$

and, if  $z$  is real,

$$\begin{aligned} \text{se}_{2n+2}(z, -q) &= (2s'_{2n+2}/B_2^{(2n+2)}) \times \\ &\times \sum_{r=0}^{\infty} (-1)^r B_{2r+2}^{(2n+2)} \text{Imag}[I_r(v'_1) I_{r+2}(v'_2)]. \end{aligned} \quad (7)$$

**13.52. Series for  $\text{fe}_{2n}(z, q)$ .** Substituting  $-iz$  for  $z$  in (1) § 13.20 gives

$$\text{Fey}_{2n}(-iz, q) = (p_{2n}/A_0^{(2n)}) \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} J_r(v'_1) Y_r(v'_2). \quad (1)$$

Consider the product  $J_r(v'_1) Y_r(v'_2)$ ; substitute the expansion of the  $Y$  function [ref. 202, p. 161, no. 61], and we get

$$\begin{aligned} J_r(v'_1) Y_r(v'_2) &= \frac{2}{\pi} [\gamma + \log_e \frac{1}{2} k] J_r(v'_1) J_r(v'_2) + \sum \text{cosines} - \\ &- i \left[ \frac{2}{\pi} z J_r(v'_1) J_r(v'_2) + \sum \text{sines} \right]. \end{aligned} \quad (2)$$

Using (2) in (1) leads to

$$\begin{aligned} & \text{Fey}_{2n}(-iz, q) \\ &= \frac{2}{\pi}(\gamma + \log_e \tfrac{1}{2}k) \text{ce}_{2n}(z, q) + (p_{2n}/A_0^{(2n)}) \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} \sum \text{cosines} - \\ & \quad - i \left[ \frac{2}{\pi} z \text{ce}_{2n}(z, q) + (p_{2n}/A_0^{(2n)}) \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} \sum \text{sines} \right]. \quad (3) \end{aligned}$$

Now, if  $z$  is real, the real and imaginary parts (even and odd functions, respectively) of (3) are linearly independent solutions of  $y'' + (a_{2n} - 2q \cos z)y = 0$ . Thus the second member of the r.h.s. must be a constant multiple of  $\text{ce}_{2n}(z, q)$ , while the imaginary member must be a constant multiple of  $\text{fe}_{2n}(z, q)$ . Hence for  $z$  real we define

$$\text{fe}_{2n}(z, q) = \text{multiple of } \text{Imag}\{\text{Fey}_{2n}(-iz, q)\}. \quad (4)$$

Now by (1) § 7.22

$$\text{fe}_{2n}(z, q) = C_{2n}(q) \left[ z \text{ce}_{2n}(z, q) + \sum_{r=0}^{\infty} f_{2r+2}^{(2n)} \sin(2r+2)z \right], \quad (5)$$

so by (1) we obtain

$$\text{fe}_{2n}(z, q) = C'_{2n}(p_{2n}/A_0^{(2n)}) \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} \text{Imag}[J_r(ke^{iz})Y_r(ke^{-iz})]. \quad (6)$$

In this and the sections which follow, the series in B.F. products are valid only if  $k \neq 0$ .

**13.53. Determination of  $C'_{2n}$ .** Differentiation term by term in (6) § 13.52 is valid since by § 13.60 the series is uniformly convergent, as also is the resulting series. Thus

$$\begin{aligned} \text{fe}'_{2n}(0, q) &= C'_{2n}(p_{2n}/A_0^{(2n)}) \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} \text{Imag}[ike^{iz}J'_r(ke^{iz})Y_r(ke^{-iz}) - \\ & \quad - ike^{-iz}J_r(ke^{iz})Y'_r(ke^{-iz})]_{z=0}, \quad (1) \end{aligned}$$

where  $J'_r(v) = dJ_r(v)/dv$ . Now  $J'_r(k)Y_r(k) - J_r(k)Y'_r(k) = -2/\pi k$ , by (1) § 13.31, so (1) gives

$$\text{fe}'_{2n}(0, q) = -C'_{2n}(p_{2n}/A_0^{(2n)}) \frac{2}{\pi} \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)}, \quad (2)$$

and, therefore,

$$C'_{2n} = -\tfrac{1}{2}\pi A_0^{(2n)} \text{fe}'_{2n}(0, q)/p_{2n} \text{ce}_{2n}(\tfrac{1}{2}\pi, q). \quad (3)$$

**13.54. Relationship between  $\text{Fey}_{2n}(-iz, q)$ ,  $\text{ce}_{2n}(z, q)$ , and  $\text{fe}_{2n}(z, q)$ .** (3) § 13.52 may be written

$$\text{Fey}_{2n}(-iz, q) = A \text{ce}_{2n}(z, q) + iB \text{fe}_{2n}(z, q). \quad (1)$$

Since  $\text{fe}_{2n}(0, q) = 0$ , we get

$$A = \text{Fey}_{2n}(0, q)/\text{ce}_{2n}(0, q). \quad (2)$$

Differentiating (1), and putting  $z = 0$ , yields

$$B = -\text{Fey}'_{2n}(0, q)/\text{fe}'_{2n}(0, q). \quad (3)$$

Hence by (1)–(3)

$$\text{Fey}_{2n}(-iz, q) = \frac{\text{Fey}_{2n}(0, q)}{\text{ce}_{2n}(0, q)} \text{ce}_{2n}(z, q) - i \frac{\text{Fey}'_{2n}(0, q)}{\text{fe}'_{2n}(0, q)} \text{fe}_{2n}(z, q). \quad (4)$$

This will be clear from (4) § 13.21.

**13.55. Series for  $\text{fe}_{2n+1}(z, q)$ ,  $\text{ge}_m(z, q)$ .** Analysis similar to that in § 13.52 leads to the following results for real values of  $z$ :

$$\begin{aligned} \text{fe}_{2n+1}(z, q) &= C'_{2n+1}(p_{2n+1}/A_1^{(2n+1)}) \times \\ &\quad \times \sum_{r=0}^{\infty} (-1)^r A_{2r+1}^{(2n+1)} \text{Imag}[J_r(v'_1)Y_{r+1}(v'_2) + J_{r+1}(v'_1)Y_r(v'_2)], \end{aligned} \quad (1)$$

$$\text{with } C'_{2n+1} = \frac{1}{2}\pi k A_1^{(2n+1)} \text{fe}'_{2n+1}(0, q)/p_{2n+1} \text{ce}'_{2n+1}(\frac{1}{2}\pi, q). \quad (2)$$

The relationship corresponding to (4) § 13.54 is obtained by writing  $2n+1$  for  $2n$ .

$$\begin{aligned} \text{ge}_{2n+1}(z, q) &= S'_{2n+1}(s_{2n+1}/B_1^{(2n+1)}) \times \\ &\quad \times \sum_{r=0}^{\infty} (-1)^r B_{2r+1}^{(2n+1)} \text{Real}[J_r(v'_1)Y_{r+1}(v'_2) - J_{r+1}(v'_1)Y_r(v'_2)], \end{aligned} \quad (3)$$

$$S_{2n+1} = -\frac{1}{2}\pi k B_1^{(2n+1)} \text{ge}_{2n+1}(0, q)/s_{2n+1} \text{se}_{2n+1}(\frac{1}{2}\pi, q), \quad (4)$$

$$\text{Gey}_{2n+1}(-iz, q) = \frac{\text{Gey}'_{2n+1}(0, q)}{\text{se}'_{2n+1}(0, q)} \text{se}_{2n+1}(z, q) + \frac{\text{Gey}_{2n+1}(0, q)}{\text{ge}_{2n+1}(0, q)} \text{ge}_{2n+1}(z, q), \quad (5)$$

$$\begin{aligned} \text{ge}_{2n+2}(z, q) &= S'_{2n+2}(s_{2n+2}/B_2^{(2n+2)}) \times \\ &\quad \times \sum_{r=0}^{\infty} (-1)^r B_{2r+2}^{(2n+2)} \text{Real}[J_r(v'_1)Y_{r+2}(v'_2) - J_{r+2}(v'_1)Y_r(v'_2)], \end{aligned} \quad (6)$$

$$S'_{2n+2} = -\frac{1}{2}\pi k^2 B_2^{(2n+2)} \text{ge}_{2n+2}(0, q)/s_{2n+2} \text{se}'_{2n+2}(\frac{1}{2}\pi, q). \quad (7)$$

The relationship corresponding to (5) is found therefrom if  $2n+2$  is written for  $2n+1$ .

**13.56. Series for  $\text{fe}_{2n}(z, -q)$ .** By (1) § 7.60

$$\text{fe}_{2n}(z, -q) = (-1)^{n+1} \text{fe}_{2n}(\frac{1}{2}\pi - z, q). \quad (1)$$

Applying the r.h.s. of (1) to (6) § 13.52 gives

$$\begin{aligned} \text{fe}_{2n}(z, -q) &= (-1)^{n+1} C'_{2n}(p_{2n}/A_0^{(2n)}) \times \\ &\quad \times \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} \text{Imag}[J_r(ike^{-is})Y_r(-ike^{is})]. \end{aligned} \quad (2)$$

The part in [ ] has the form  $x+iy$ , so if  $z$  is real, (2) is unaltered if we write  $-i$  for  $i$  and  $(-1)^n$  for  $(-1)^{n+1}$ . Thus for  $z$  real

$$\begin{aligned} \text{fe}_{2n}(z, -q) &= (-1)^n C'_{2n}(p_{2n}/A_0^{(2n)}) \times \\ &\quad \times \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} \text{Imag}[J_r(-ike^{iz})Y_r(ike^{-iz})]. \end{aligned} \quad (3)$$

$$\text{Now} \quad J_r(-ike^{iz}) = i^{-r} I_r(ke^{iz}) \quad (4)$$

$$\text{and} \quad Y_r(ike^{-iz}) = i^{-r} \left[ -\frac{2}{\pi} K_r(ke^{-iz}) + (-1)^r i I_r(ke^{-iz}) \right]. \quad (5)$$

Using (4), (5) in (3) leads to

$$\begin{aligned} \text{fe}_{2n}(z, -q) &= C'_{2n}(p'_{2n}/A_0^{(2n)}) \times \\ &\quad \times \left\{ \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} I_r(ke^{iz}) I_r(ke^{-iz}) - \frac{2}{\pi} \sum_{r=0}^{\infty} A_{2r}^{(2n)} \text{Imag}[I_r(ke^{iz}) K_r(ke^{-iz})] \right\} \end{aligned} \quad (6)$$

$$= C'_{2n}[\text{ce}_{2n}(z, -q) - 2 \text{Imag}\{\text{Fek}_{2n}(-iz, -q)\}] \quad (7)$$

$$= C'_{2n}[\text{ce}_{2n}(z, -q) - 2 \text{fek}_{2n}(z, -q)], \quad (8)$$

where the definition of  $\text{fek}_{2n}(z, -q)$  is obvious.

Replacing the  $K$  functions in (6) by their expansions [ref. 202, p. 165] leads to

$$\text{fe}_{2n}(z, -q) = \text{const.}[(\frac{1}{2}\pi - z)\text{ce}_{2n}(z, -q) + \text{a sine series}], \quad (9)$$

and this has the same form as (2) § 7.60.

**13.57. Series for  $\text{fe}_{2n+1}(z, -q)$ ,  $\text{ge}_m(z, -q)$ .** Applying (3) § 7.60 to (3) § 13.55 gives

$$\begin{aligned} \text{fe}_{2n+1}(z, -q) &= S'_{2n+1}(s'_{2n+1}/B_1^{(2n+1)}) \times \\ &\quad \times \sum_{r=0}^{\infty} (-1)^r B_{2r+1}^{(2n+1)} \text{Real}[J_r(iv'_2)Y_{r+1}(-iv'_1) - J_{r+1}(iv'_2)Y_r(-iv'_1)]. \end{aligned} \quad (1)$$

If  $z$  is real, (1) is unaltered if we write  $-i$  for  $i$ , since the real part in [ ] is unaffected. Doing this and following on the lines of § 13.56 leads to

$$\text{fe}_{2n+1}(z, -q) = S'_{2n+1}[\text{ce}_{2n+1}(z, -q) - 2 \text{Imag}\{\text{Fek}_{2n+1}(-iz, -q)\}] \quad (2)$$

$$= S'_{2n+1}[\text{ce}_{2n+1}(z, -q) - 2 \text{fek}_{2n+1}(z, -q)] \quad (z \text{ real}). \quad (3)$$

Similarly we obtain

$$\text{ge}_{2n+1}(z, -q) = C'_{2n+1}[\text{se}_{2n+1}(z, -q) - 2 \text{Real}\{\text{Gek}_{2n+1}(-iz, -q)\}] \quad (4)$$

$$= C'_{2n+1}[\text{se}_{2n+1}(z, -q) - 2 \text{gek}_{2n+1}(z, -q)] \quad (z \text{ real}), \quad (5)$$

$$ge_{2n+2}(z, -q) = S'_{2n+2}[se_{2n+2}(z, -q) - 2 \operatorname{Real}\{\operatorname{Gek}_{2n+2}(-iz, -q)\}] \quad (6)$$

$$= S'_{2n+2}[se_{2n+2}(z, -q) - 2 \operatorname{gek}_{2n+2}(z, -q)] \quad (z \text{ real}). \quad (7)$$

In each case by using the expansions for the  $K$ -Bessel functions, as at (9) § 13.56, the forms in § 7.60 may be obtained.

**13.60. Convergence of solutions.** By analysis similar to that given below, all the B.F. product series in this chapter may be proved absolutely and uniformly convergent in any finite region of the  $z$ -plane. We shall exemplify this point, using the series

$$\sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} J_r(v_1) Y_r(v_2). \quad (1)$$

Then by (1), (2) § 8.50 we get

$$J_r(v_1) Y_r(v_2) \sim r^{-1} e^{-2rz} \quad (r \gg |v_1| \text{ or } |v_2|). \quad (2)$$

Using (2), and (4) § 3.21, the ratio of the  $(r+1)$ th to the  $r$ th term is

$$\left| \frac{J_{r+1}(v_1) Y_{r+1}(v_2) A_{2r+2}^{(2n)}}{J_r(v_1) Y_r(v_2) A_{2r}^{(2n)}} \right| \simeq \frac{|k^2 e^{-2z}|}{4(r+1)^2} \rightarrow 0, \quad \text{as } r \rightarrow +\infty, \quad (3)$$

for all real or complex  $z$  provided  $R(z)$  is finite. Hence under this condition series (1) is absolutely convergent. By applying the ' $M$ ' test the convergence may be proved uniform. It follows that

$$\sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} J_r(ke^{iz}) Y_r(ke^{-iz}) \quad (4)$$

is absolutely and uniformly convergent, provided  $R(iz)$  is finite, i.e.  $\operatorname{Im}g(z)$  is finite.

By virtue of uniform convergence, it follows that the functions represented by the B.F. product series are continuous in any finite region of the  $z$ -plane.

**13.61. Advantages of B.F. product series over those in Chapter VIII.** These are as follows:

1. The product series converge more rapidly than those with argument  $2k \cosh z$ ,  $2k \sinh z$ . The rate of convergence increases with increase in  $z$  (real).
2. The product series for  $\operatorname{Fey}_m$ ,  $\operatorname{Fek}_m$ ,  $\operatorname{Gey}_m$ ,  $\operatorname{Gek}_m$  converge uniformly in any finite region of the  $z$ -plane, including the origin. The other series do not converge uniformly in a restricted region, including the origin.

3. By virtue of (1), (2), the product series are preferable for calculating the values of the functions. This feature is illustrated vividly in Table 22.

TABLE 22. *Computation of  $\text{Fek}_0(z, -4)$ ;  $k = 2, q = 4$* 

$r$	$z = 0, 2k \cosh z = 4$		$z = \log_e 2, 2k \cosh z = 5$	
	$\frac{\text{ce}_0(0, 4)}{A_0} (-1)^r \times$ $\times K_{2r}(2k \cosh z)$	$\frac{\text{ce}_0(0, 4)\text{ce}_0(\frac{1}{2}\pi, 4)}{A_0^2} \times$ $\times I_r(ke^{-z})K_r(ke^z)$	As in column 2	As in column 3
0	0.00078 0079	+0.04189 15	0.00025 801	+0.00227 970
1	130 1687	-0.03841 39	39 706	-0. 121 818
2	93 6560	+0.00607 35	22 965	+0. 8 215
3	67 359 .	-0. 47 80	12 127	-0. 230

5	39 90 ..	-0. 07	3 30 .	
6			1 7 ..	
Sum	+0.0046 . . . . .	+0.00909 51	0.00111 905	+0.00114 137

When  $z = 0$  the  $K_{2r}$  series, being non-uniformly convergent, converges so slowly that six terms contribute much less than three of the  $I_r K_r$  series. In columns 3, 5 the rapidity of convergence of the  $I_r K_r$  series is strikingly displayed, the value of the function being obtained to at least seven decimal places using only four terms. See also [8].

MATHIEU FUNCTIONS

**14.10. Evaluation of  $\int_0^z y \cosh 2u \, du$ , when  $y$  satisfies**

$$y'' - (a - 2q \cosh 2u)y = 0.$$

Integrating the D.E. with respect to  $u$  from 0 to  $z$ , we obtain

$$[y']_0^z - a \int_0^z y \, du + 2q \int_0^z y \cosh 2u \, du = 0, \quad (1)$$

so 
$$\int_0^z y \cosh 2u \, du = \frac{a}{2q} \int_0^z y \, du - \frac{1}{2q} [y'(z) - y'(0)], \quad (2)$$

where  $y$  is *any* solution. In particular, if  $y = \text{Ce}_{2n}(u, q)$ ,

$$\int_0^z \text{Ce}_{2n}(u, q) \, du = A_0^{(2n)} z + \sum_{r=1}^{\infty} \frac{1}{2r} A_{2r}^{(2n)} \sinh 2rz, \quad (3)$$

$$\frac{d}{du} \text{Ce}_{2n}(u, q) \Big|_{u=0}^{u=z} = \sum_{r=1}^{\infty} 2r A_{2r}^{(2n)} \sinh 2rz. \quad (4)$$

Substituting (3), (4) into (2) gives

$$\begin{aligned} \int_0^z \text{Ce}_{2n}(u, q) \cosh 2u \, du &= \frac{1}{2} A_2^{(2n)} z + \frac{1}{4} A_0^{(2n)} \sinh 2z + \\ &+ \frac{1}{4} \sum_{r=1}^{\infty} \frac{1}{r} (A_{2r+2}^{(2n)} + A_{2r-2}^{(2n)}) \sinh 2rz, \end{aligned} \quad (5)$$

by (1) § 3.10.

In a similar way for  $y'' + (a - 2q \cos 2u)y = 0$ , we find that

$$\int_0^z y \cos 2u \, du = \frac{a}{2q} \int_0^z y \, du + \frac{1}{2q} [y'(z) - y'(0)], \quad (6)$$

and in particular, when  $y = \text{ce}_{2n}(u, q)$ , the r.h.s. is

$$\frac{1}{2} A_2^{(2n)} z + \frac{1}{4} A_0^{(2n)} \sin 2z + \frac{1}{4} \sum_{r=1}^{\infty} \frac{1}{r} (A_{2r+2}^{(2n)} + A_{2r-2}^{(2n)}) \sin 2rz. \quad (7)$$

**14.20. Product integrals.** We commence with the equations

$$y_1'' - (a - 2q_1 \cosh 2u)y_1 = 0 \quad (1)$$

and 
$$y_2'' - (a - 2q_2 \cosh 2u)y_2 = 0, \quad (2)$$

the  $a$  being the same but  $q_1 \neq q_2$ . Multiplying (1) by  $y_2$ , (2) by  $y_1$ , subtracting and integrating with respect to  $u$  from  $z_1$  to  $z_2$ , we get

$$2(q_2 - q_1) \int_{z_1}^{z_2} y_1(u)y_2(u) \cosh 2u \, du = [y_1'(u)y_2(u) - y_2'(u)y_1(u)]_{z_1}^{z_2}. \quad (3)$$

When the fundamental ellipse becomes a circle, (3) degenerates to the well-known form for the Bessel functions [202, chap. vi].

If in (1), (2)  $q_1 = q_2$  and  $y_1, y_2$  are independent solutions of the same equation, with  $z_1$  constant and  $z_2 = z$  variable, we get

$$y_1'(z)y_2(z) - y_2'(z)y_1(z) = y_1'(z_1)y_2(z_1) - y_2'(z_1)y_1(z_1) = c^2, \text{ a constant.} \quad (4)$$

For given functions  $y_1, y_2$ ,  $c^2$  is independent of  $z$ , but not of  $q$ . By (4)

$$\frac{d}{du} [\log(y_1/y_2)] = c^2/y_1 y_2, \quad (5)$$

so 
$$\int^z du/y_1 y_2 = \frac{1}{c^2} \log(y_1/y_2). \quad (6)$$

Taking  $y_1 = \text{Ce}_{2n+1}(u, q)$ ,  $y_2 = \text{Fe}_{2n+1}(u, q)$ , (6) asserts that

$$\int^z du / [\text{Ce}_{2n+1}(u) \text{Fe}_{2n+1}(u)] = \frac{1}{c^2} \log[\text{Ce}_{2n+1}(z)/\text{Fe}_{2n+1}(z)]. \quad (7)$$

Again, from (4),  $y_1' y_2 - y_2' y_1 = c^2$ , so dividing throughout by  $y_2^2$  gives

$$(y_1'/y_2) - (y_2' y_1/y_2^2) = c^2/y_2^2, \quad (8)$$

or 
$$\frac{d(y_1/y_2)}{du} = c^2/y_2^2. \quad (9)$$

Integrating (9) leads to

$$y_1/y_2 = c^2 \int^z du/y_2^2 + A, \quad (10)$$

or 
$$y_1 = c^2 y_2 \int^z du/y_2^2 + A y_2. \quad (11)$$

This gives one solution in terms of the other, but it is a troublesome form to use in practice. The lower limit is an arbitrary constant, related to  $A$ .

† For solutions of Bessel's equation the equivalent of (4) takes the form [202, p. 156]  $y_1' y_2 - y_2' y_1 = \text{a constant}/z$ . The absence of  $z^{-1}$  on the r.h.s. of (4) is by virtue of Mathieu's equation having no differential of the first order.

The results herein are valid for solutions of

$$y'' + (a - 2q \cos 2u)y = 0,$$

provided that  $\cosh 2u$  is replaced by  $-\cos 2u$ .

**14.21. Theorem.** If  $y_1(u)$ ,  $y_2(u)$  are solutions of

$$y'' - (a - 2q \cosh 2u)y = 0$$

for the same  $a$ , corresponding respectively to  $q_1$ ,  $q_2$ , such that  $y'_1(0)y_2(0) - y'_2(0)y_1(0) = 0$ , and either  $y_1(z, q_1) = y_2(z, q_2) = 0$  or  $y'_1(z, q_1) = y'_2(z, q_2) = 0$ , then

$$\int_0^z y_1(u)y_2(u)\cosh 2u \, du = 0. \quad (1)$$

This follows from (3) § 14.20. If  $y_1(u) = y_2(u)$ ,

$$\int_0^z y_1^2(u)\cosh 2u \, du \neq 0. \quad (2)$$

We now proceed to evaluate this integral.

In (3) § 14.20 take  $\Delta q = (q_2 - q_1)$  to be small,†  $z_1 = 0$ ,  $z_2 = z$ , then we have

$$[y'_1(u)y_2(u) - y'_2(u)y_1(u)]_0^z - 2\Delta q \int_0^z y_1(u)y_2(u)\cosh 2u \, du = 0. \quad (3)$$

By Taylor's theorem

$$y_2 = y_1 + \Delta q \frac{\partial y_1}{\partial q} + \frac{(\Delta q)^2}{2!} \frac{\partial^2 y_1}{\partial q^2} + \dots \quad (4)$$

Substituting into (3) and neglecting terms in  $(\Delta q)^2, \dots$  leads to

$$\begin{aligned} & \left[ y'_1 \left( y_1 + \Delta q \frac{\partial y_1}{\partial q} \right) - y'_1 \left( y'_1 + \Delta q \frac{\partial}{\partial u} \frac{\partial y_1}{\partial q} \right) \right]_0^z - \\ & - 2\Delta q \int_0^z y_1 \left( y_1 + \Delta q \frac{\partial y_1}{\partial q} \right) \cosh 2u \, du = 0. \end{aligned} \quad (5)$$

Dividing throughout by  $\Delta q$  and letting  $\Delta q$  tend to zero yields, with  $y$  for  $y_1$ ,

$$\left[ \frac{\partial y}{\partial u} \frac{\partial y}{\partial q} - y \frac{\partial}{\partial u} \frac{\partial y}{\partial q} \right]_0^z - 2 \int_0^z y^2(u) \cosh 2u \, du = 0. \quad (6)$$

$$\text{Hence} \quad \int_0^z y^2(u) \cosh 2u \, du = \frac{1}{2} \left[ \frac{\partial y}{\partial u} \frac{\partial y}{\partial q} - y \frac{\partial}{\partial u} \left( \frac{\partial y}{\partial q} \right) \right]_0^z. \quad (7)$$

$\partial y / \partial q$  is not found by differentiating the coefficients in the series for  $y$ , since both  $q$ ,  $a$  vary on a characteristic curve.

†  $y_2 \rightarrow y_1$  as  $\Delta q \rightarrow 0$ .

**14.22. Example.** Evaluate (7) § 14.21 when  $y = \text{Ce}_{2n}(u)$ , given that  $\text{Ce}_{2n}(\xi_0, q) = 0$ , the upper limit being  $z = \xi_0$ . Here  $\partial y / \partial u|_{u=0} = 0$ , since all terms in the series vanish at the origin. Then

$$\int_0^{\xi_0} y^2 \cosh 2u \, du = \frac{1}{2} \left[ \frac{\partial y}{\partial u} \frac{\partial y}{\partial q} \right]_{u=\xi_0} + \frac{1}{2} \left[ y \frac{\partial}{\partial u} \left( \frac{\partial y}{\partial q} \right) \right]_{u=0} \quad (1)$$

$$= \frac{1}{2} \text{Ce}'_{2n}(\xi_0, q) \left( \frac{\partial y}{\partial q} \right)_{u=\xi_0} + \frac{1}{2} \text{Ce}_{2n}(0, q) \left[ \frac{\partial}{\partial u} \left( \frac{\partial y}{\partial q} \right) \right]_{u=0}, \quad (2)$$

where, with  $a$  constant,

$$\partial y / \partial q = \lim_{\substack{\Delta q \rightarrow 0 \\ \beta \rightarrow 0}} \{ [\text{Ce}_{2n+\beta}(u, q + \Delta q) - \text{Ce}_{2n}(u, q)] / \Delta q \}. \quad (3)$$

The only way of evaluating (2) seems to be by a numerical process.

**14.23. Evaluation of  $\int_0^z (y'^2 + ay^2) \, du$ , when  $y$  satisfies**

$$y'' - (a - 2q \cosh 2u)y = 0.$$

The D.E. may be written

$$-y'' + ay = (2q \cosh 2u)y. \quad (1)$$

Multiplying both sides of (1) by  $y$ , and integrating with respect to  $u$  from 0 to  $z$ , yields

$$- \int_0^z y \, dy' + a \int_0^z y^2 \, du = 2q \int_0^z y^2 \cosh 2u \, du. \quad (2)$$

Thus

$$\int_0^z (y'^2 + ay^2) \, du = [yy']_0^z + 2q \int_0^z y^2 \cosh 2u \, du \quad (3)$$

$$= [yy']_0^z + q \left[ \frac{\partial y}{\partial u} \frac{\partial y}{\partial q} - y \frac{\partial}{\partial u} \left( \frac{\partial y}{\partial q} \right) \right]_0^z, \quad (4)$$

by (7) § 14.21.

**14.24. Evaluate (4) § 14.23 if  $y = \text{Ce}_{2n}(u, q)$ , given that  $\text{Ce}_{2n}(\xi_0, q) = 0$ ,  $z = \xi_0$ . Since  $\text{Ce}_{2n}(\xi_0, q) = 0$ , and  $\text{Ce}'_{2n}(0, q) = 0$ , the first member on the r.h.s. of (4) § 14.23 vanishes. Hence by (7) § 14.21, (2) § 14.22 and (4) § 14.23**

$$\int_0^{\xi_0} [\text{Ce}_{2n}^{\prime 2}(u, q) + a \text{Ce}_{2n}^2(u, q)] \, du = 2q \text{ times (2) § 14.22.} \quad (1)$$

**14.30. Integrals involving  $\sinh 2u$ .** Let  $y$  be a solution of the differential equation in § 14.23. Differentiating

$$\phi(u) = y'^2(u) - (a - 2q \cosh 2u)y^2(u) \quad (1)$$

with respect to  $u$ , we obtain

$$\frac{d\phi}{du} = 2y'y'' + 4q(yy' \cosh 2u + y^2 \sinh 2u) - 2ayy' \quad (2)$$

$$= 2y'[y'' - (a - 2q \cosh 2u)y] + 4qy^2 \sinh 2u = 4qy^2 \sinh 2u. \quad (3)$$

Hence

$$\begin{aligned} 4q \int^z y^2 \sinh 2u \, du &= y'^2(z) - (a - 2q \cosh 2z)y^2(z) \\ &= y'^2(z) - y(z)y''(z). \end{aligned} \quad (4)$$

Integrating by parts gives

$$\int^z y^2 \sinh 2u \, du = 2 \int^z y^2 \cosh u \, d \cosh u \quad (5)$$

$$= 2 \left[ y^2 \cosh^2 z - \frac{1}{2} \int^z y^2 \sinh 2u \, du - 2 \int^z yy' \cosh^2 u \, du \right]. \quad (6)$$

Therefore

$$\int^z y^2 \sinh 2u \, du = y^2(z) \cosh^2 z - 2 \int^z yy' \cosh^2 u \, du. \quad (7)$$

Hence by (4), (7) we find that

$$4q \int^z yy' \cosh^2 u \, du = (q + \frac{1}{2}a)y^2(z) - \frac{1}{2}y'^2(z). \quad (8)$$

Since  $\cosh^2 u = \frac{1}{2}(\cosh 2u + 1)$ , (8) may be written

$$4q \int^z yy' \cosh 2u \, du = (2q + a)y^2(z) - y'^2(z) - 4q \int^z yy' \, du \quad (9)$$

$$= ay^2(z) - y'^2(z). \quad (10)$$

**14.40. Integrals for the ordinary Mathieu functions.** If  $v$  is a solution of  $v'' + (a - 2q \cos 2u)v = 0$ , the integrals corresponding to (4), (8), (10) § 14.30 are

$$4q \int^z v^2 \sin 2u \, du = v'^2(z) + (a - 2q \cos 2z)v^2(z) \quad (1)$$

$$= v'^2(z) - v(z)v''(z), \quad (2)$$

$$4q \int^z vv' \cos^2 u \, du = (\frac{1}{2} + \frac{1}{2}a)v^2(z) + \frac{1}{2}v'^2(z), \quad (3)$$

$$4q \int^z vv' \cos 2u \, du = av^2(z) + v'^2(z). \quad (4)$$

Using (2) with  $v = ce_m(u, q)$  or  $se_m(u, q)$ , we find that

$$\int_0^{2\pi} ce_m^2(u) \sin 2u \, du = \int_0^{2\pi} se_m^2(u) \sin 2u \, du = 0. \quad (5)$$

Using (4) leads to

$$\int_0^{2\pi} ce_m(u) ce'_m(u) \cos 2u \, du = \int_0^{2\pi} se_m(u) se'_m(u) \cos 2u \, du = 0. \quad (6)$$

From § 9.40 we have

$$\int_0^{2\pi} ce_m^2(u) \cos 2u \, du = \pi \Theta_m; \quad \int_0^{2\pi} se_m^2(u) \cos 2u \, du = \pi \Psi'_m. \quad (7)$$

**14.41. Evaluation of**  $\int_0^{2\pi} ce_m'^2(z, q) \, dz, \int_0^{2\pi} se_m'^2(z, q) \, dz$ . We have

$$\int_0^{2\pi} y'^2(z) \, dz = \int_0^{2\pi} y' \, dy = [yy']_0^{2\pi} - \int_0^{2\pi} yy'' \, dy. \quad (1)$$

If  $y = ce_m(z, q)$  or  $se_m(z, q)$ , the third member of (1) vanishes at both limits. Since  $y$  is a solution of  $y'' + (a - 2q \cos 2z)y = 0$ , the first and last members of (1) give

$$\int_0^{2\pi} y'^2(z) \, dz = \int_0^{2\pi} (a - 2q \cos 2z) y^2 \, dy. \quad (2)$$

The evaluation of the r.h.s. is obtained from (1) § 2.21, and (7) § 14.40, so we get

$$\int_0^{2\pi} y'^2(z) \, dz = \pi \left[ a - 2q \left( \frac{\Theta_m}{\Psi'_m} \right) \right] = \pi \left( \frac{\vartheta_m}{\varpi_m} \right), \quad (3)$$

if  $y = ce_m$  or  $se_m$ .

**14.42. Evaluation of**  $\int_0^{2\pi} ce_m(z, q) se'_n(z, q) \, dz, \int_0^{2\pi} se_n(z, q) ce'_m(z, q) \, dz$ .

First we have

$$\int_0^{2\pi} ce_m se'_n \, dz = [ce_m se_n]_0^{2\pi} - \int_0^{2\pi} se_n ce'_m \, dz, \quad (1)$$

by partial integration. The member in [ ] vanishes at the limits. Hence

$$\int_0^{2\pi} ce_m se'_n \, dz = - \int_0^{2\pi} se_n ce'_m \, dz. \quad (2)$$

Now

$$\int_0^{2\pi} ce_{2m} se'_{2n} dz = \int_0^{2\pi} \left[ \sum_{r=0}^{\infty} A_{2r}^{(2m)} \cos 2rz \sum_{r=1}^{\infty} 2r B_{2r}^{(2n)} \cos 2rz \right] dz \quad (3)$$

$$= \sum_{r=1}^{\infty} 2r \int_0^{2\pi} A_{2r}^{(2m)} B_{2r}^{(2n)} \cos^2 2rz dz, \quad (4)$$

since the other integrals vanish,  $\sum$  being moved outside the integral sign by virtue of uniform convergence. Therefore by (2), (4)

$$\int_0^{2\pi} ce_{2m} se'_{2n} dz = - \int_0^{2\pi} se_{2n} ce'_{2m} dz = \pi \sum_{r=1}^{\infty} 2r A_{2r}^{(2m)} B_{2r}^{(2n)}. \quad (5)$$

In a similar way we find that

$$\begin{aligned} \int_0^{2\pi} ce_{2m+1} se'_{2n+1} dz &= - \int_0^{2\pi} se_{2n+1} ce'_{2m+1} dz \\ &= \pi \sum_{r=0}^{\infty} (2r+1) A_{2r+1}^{(2m+1)} B_{2r+1}^{(2n+1)} \end{aligned} \quad (6)$$

$$\text{and} \quad \int_0^{2\pi} ce_m ce'_n dz = \int_0^{2\pi} se_m se'_n dz = 0. \quad (7)$$

These results are valid for  $m \neq n$  or  $m = n$ .

**14.50. An integral identity.** In § 14.20 we showed that if  $y_1, y_2$  were solutions of  $y'' - (a - 2q \cosh 2u)y = 0$  for the same  $a, q$ , then for all  $u$

$$y'_1 y_2 - y'_2 y_1 \equiv c^2, \quad \text{a constant.} \quad (1)$$

Squaring both sides of (1) gives

$$y_1'^2 y_2^2 + y_2'^2 y_1^2 - 2y_1' y_2' y_1 y_2 \equiv c^4. \quad (2)$$

Now, by § 10.76,

$$y'_1 y'_2 = \xi_{1,2}(0) - y_1(z) y_2(z) \chi(z) + 4q \int_0^z y_1(u) y_2(u) \sinh 2u du, \quad (3)$$

where  $\xi_{1,2}(0) = y_1'(0) y_2'(0) + y_1(0) y_2(0) \chi(0)$ . Using (3) in (2) leads† to

$$\begin{aligned} c^4 &\equiv y_2^2(z) \xi_{1,1}(0) + y_1^2(z) \xi_{2,2}(0) - 2y_1(z) y_2(z) \xi_{1,2}(0) + \\ &\quad + 4q \int_0^z [y_2(z) y_1(u) - y_1(z) y_2(u)]^2 \sinh 2u du. \end{aligned} \quad (4)$$

† With the aid of (4) § 14.30.

Taking the initial conditions  $y_1(0) = y_2'(0) = 1$ ,  $y_1'(0) = y_2(0) = 0$ , we find that  $\xi_{1,1}(0) = (2q-a)$ ,  $\xi_{2,2}(0) = 1$ ,  $\xi_{1,2}(0) = 0$ ,  $c^4 = 1$ . Hence (4) becomes

$$y_1^2(z) + (2q-a)y_2^2(z) + 4q \int_0^z [y_2(z)y_1(u) - y_1(z)y_2(u)]^2 \sinh 2u \, du \equiv 1, \quad (5)$$

or

$$4q \int_0^z [y_2(z)y_1(u) - y_1(z)y_2(u)]^2 \sinh 2u \, du \equiv 1 - y_1^2(z) + (a-2q)y_2^2(z). \quad (6)$$

For the equation  $y'' + (a-2q \cos 2z)y = 0$ , the identity corresponding to (6) is

$$4q \int_0^z [y_2(z)y_1(u) - y_1(z)y_2(u)]^2 \sin 2u \, du \equiv 1 - y_1^2(z) - (a-2q)y_2^2(z). \quad (7)$$

If  $a, q$  are fixed, (6), (7) are valid for all real finite values of  $z$ . When  $q = 0$ , (7) degenerates to

$$y_1^2(z) + ay_2^2(z) = 1, \quad (8)$$

while the equation becomes

$$y'' + ay = 0, \quad (9)$$

and the appropriate solutions which conform with (8) are

$$y(z) = \cos a^{\frac{1}{2}}z, \quad \sin a^{\frac{1}{2}}z/a^{\frac{1}{2}}$$

respectively.

## PART II

### APPLICATIONS OF MATHIEU FUNCTIONS

#### XV

#### APPLICATIONS OF $y'' + (a - 2q \cos 2z)y = 0$

**15.10. Amplitude distortion in moving-coil loud-speaker.** A conventional diagram of this apparatus is shown in Fig. 20 A. A sinusoidal current, of low audio frequency, in the coil causes it to vibrate axially about a central or equilibrium position. For absence of distortion arising from amplitude of motion, the amplitude must be proportional to that of the coil current. This condition is fulfilled if the total magnetic flux passing radially through the coil remains constant throughout its travel.† When the axial length of the coil is equal to that of the outer pole face (Fig. 20 B), and the amplitude is relatively great, i.e. the sound output is large, an appreciable length of the coil moves into the leakage field at each side of the outer pole. The amplitude cannot then be proportional to the current, since the field decreases rapidly with increase in axial distance from either side of the outer pole. In practice the coil usually tends to move into the weaker part of the field, but its excursion is limited by the axial restoring force exerted by the centring spider (not shown), and the outer surround which supports the diaphragm. By virtue of this superimposed unidirectional motion, speech and music are reproduced with perceptible distortion because the axial constraint is non-linear for large coil displacement.‡ If, however, the axial length of the coil is adequately greater than that of the outer pole (Fig. 20 D), the magnetic flux passing radially through the coil is almost constant throughout the travel. Then the effect described above is negligible, being counteracted easily by the axial restoring force. A well-designed loud-speaker satisfies this requirement [201], provided the coil amplitude does not exceed the linearity limits of the axial control.

† It has been tacitly assumed that the axial constraint is proportional to the displacement of the coil.

‡ When the coil current arises from speech or music, intermodulation occurs between the various component frequencies, owing to the constraint-displacement relationship being non-linear. The distortion is unpleasant.

FIG. 20 A-D. Schematic diagrams for moving-coil loud-speaker.

**15.11. The equation of motion.** To study the phenomenon, described in § 15.10, analytically, we consider a relatively narrow coil situated in a radial magnetic field which decreases linearly† from the outer side of the centre pole (Fig. 21) towards the left, i.e. away from the magnet. The axial force on the coil due to a current  $I_0 \cos 2\omega t$  is

$$f = 2\pi r n c \xi I_0 \cos 2\omega t, \quad (1)$$

where

$r$  = mean coil radius,

$n$  = number of coil turns, uniformly spaced,

† In practice the relationship between flux and axial distance takes the form shown in Fig. 20 c.

$B = c\xi$  = magnetic flux density when coil centre is distant  $\xi$  from the origin,

$c$  = slope of line in Fig. 21.

FIG. 21. Assumed relation between flux density  $B$  and distance from outer face of magnet in Fig. 20.

For simplicity we assume that:

- (a) the axial restoring force on the diaphragm is negligible;
- (b) the mechanical loss is negligible;
- (c) the electrical impedance of the circuit external to the coil is large enough to preserve constant current whatever  $\xi$ , i.e. the back e.m.f. induced in the coil by virtue of motion in the magnetic field is small compared with the potential difference applied to the circuit.

If  $m_e$  is the effective mass of the coil and diaphragm, the equation of motion is

$$m_e \frac{d^2 \xi}{dt^2} - 2\pi r n c \xi I_0 \cos 2\omega t = 0. \quad (2)$$

Writing  $z = \omega t$ ,  $q = \pi r n c I_0 / \omega^2 m_e$ , (2) becomes

$$\frac{d^2 \xi}{dz^2} - (2q \cos 2z) \xi = 0. \quad (3)$$

If a linear axial restoring force  $s$  per unit axial displacement is present, the term  $s\xi$  must be added to the l.h.s. of (2). Then we have

$$\frac{d^2 \xi}{dz^2} + (a - 2q \cos 2z) \xi = 0 \quad (4)$$

with  $a = s/\omega^2 m_e$ . In addition, if linear damping  $r_e$  per unit axial velocity is present, the equation of motion is

$$m_e \frac{d^2 \xi}{dt^2} + r_e \frac{d \xi}{dt} + s \xi - 2\pi r n c \xi I_0 \cos 2\omega t = 0, \quad (5)$$

$$\text{or} \quad \frac{d^2 \xi}{dz^2} + 2\kappa \frac{d \xi}{dz} + (a - 2q \cos 2z)\xi = 0, \quad (6)$$

where  $2\kappa = r_e/\omega m_e$ .

Under the simplifying assumptions given above, the motion of the coil in a linearly decreasing radial magnetic field is defined by (3). As a practical value of  $q$  we take 0.16, so the equation to be solved is

$$\frac{d^2 \xi}{dz^2} - (0.32 \cos 2z)\xi = 0. \quad (7)$$

**15.12. Solution of (7) § 15.11.** From Fig. 8 we see that the point  $a = 0$ ,  $q = 0.16$  lies in a stable region of the plane between  $a_0$  and  $b_1$ . By (1) § 4.74 with  $\nu = \beta$ ,  $a = 0$ , we obtain

$$\beta^2 \simeq q^2/2(1 - \beta^2),$$

from which we find that

$$\beta \simeq 0.1138. \quad (1)$$

For the first solution, in accordance with 1° § 4.70 we take

$$\xi_1 = \sum_{r=-\infty}^{\infty} c_{2r} \cos(2r + 0.114)z. \quad (2)$$

By (1) § 4.17 the recurrence formula for the  $c$  is

$$(2r + 0.114)^2 c_{2r} + 0.16(c_{2r+2} + c_{2r-2}) = 0. \quad (3)$$

Neglecting  $c_6$ , with  $r = 2$ , we get

$$\begin{aligned} c_2 &= -4.114^2 \times 6.25 c_4 \\ &= -1.057 \times 10^2 c_4. \end{aligned} \quad (4)$$

$$\begin{aligned} r = 1 \quad c_0 &= 2.114^2 \times 6.25 \times 1.057 \times 10^2 c_4 - c_4 \\ &= 2.95 \times 10^3 c_4. \end{aligned} \quad (5)$$

$$\text{Thus} \quad c_2 = -3.58 \times 10^{-2} c_0 \quad (6)$$

$$\text{and} \quad c_4 = 3.39 \times 10^{-4} c_0. \quad (7)$$

Neglecting  $c_{-6}$ , with  $r = -3$

$$\begin{aligned} c_{-4} &= -5.886^2 \times 6.25 c_{-6} \\ &= -2.165 \times 10^2 c_{-6}. \end{aligned} \quad (8)$$

$$\begin{aligned} r = -2 \quad c_{-2} &= 3.886^2 \times 6.25 \times 2.165 \times 10^2 c_{-6} - c_{-6} \\ &= 2.04 \times 10^4 c_{-6}. \end{aligned} \quad (9)$$

$$r = -1 \quad c_0 = -1.886^2 \times 6.25 \times 2.04 \times 10^4 c_{-6} - c_{-4} \\ = -4.55 \times 10^5 c_{-6}. \quad (10)$$

Thus

$$c_{-2} = -4.5 \times 10^{-2} c_0, \quad (11)$$

$$c_{-4} = 4.77 \times 10^{-4} c_0, \quad (12)$$

$$c_{-6} = -2.2 \times 10^{-6} c_0. \quad (13)$$

If in (3) we put  $r = 0$ ,  $\beta$  for 0.114, and insert the values of  $c_2$ ,  $c_{-2}$ , we obtain

$$c_0 \beta^2 = -0.16(c_2 + c_{-2}) = 0.16 \times 8.08 \times 10^{-2} c_0,$$

$$\text{so,} \quad \beta = 0.1137, \quad (14)$$

which checks the value at (1) and also the computation in general—up to a point!

Substituting for  $\beta$  and the  $c$  in (2), the first solution is

$$\xi_1 = c_0 [\cos 0.114z - 4.5 \times 10^{-2} \cos 1.886z - \\ - 3.58 \times 10^{-2} \cos 2.114z + \dots]. \quad (15)$$

By 1° § 4.70 the second solution is

$$\xi_2 = c_0 [\sin 0.114z + 4.5 \times 10^{-2} \sin 1.886z - \\ - 3.58 \times 10^{-2} \sin 2.114z - \dots]. \quad (16)$$

By § 4.71, (15), (16) are multiples of  $\text{ce}_{0.114}(z, 0.16)$  and  $\text{se}_{0.114}(z, 0.16)$ , respectively. Using (3) § 4.72, we have

$$K \simeq 1/c_0 [1 + 0.045^2 + 0.036^2]^{\frac{1}{2}} \simeq 1/1.002 c_0. \quad (17)$$

Hence

$$\xi_1 = 1.002 c_0 \text{ce}_{0.114}(z, 0.16) \quad \text{and} \quad \xi_2 = 1.002 c_0 \text{se}_{0.114}(z, 0.16), \quad (18)$$

and the complete solution with two arbitrary constants is

$$\xi = A \xi_1 + B \xi_2. \quad (19)$$

**15.13. Initial conditions.** We take  $\xi = \xi_0$ ,  $\dot{\xi} = 0$  at  $t = 0$ , i.e. when  $z = 0$ . Then by (15), (16), (19) § 15.12 the first condition gives

$$\xi_0 = A c_0 (1 - 0.045 - 0.0358),$$

$$\text{so} \quad A = 1.088 \xi_0 / c_0. \quad (1)$$

The second condition gives  $B = 0$ . Hence the appropriate solution of the problem is

$$\xi = 1.088 \xi_0 [\cos 0.114z - 0.045 \cos 1.886z - 0.036 \cos 2.114z + \dots] \quad (2)$$

$$= 1.09 \xi_0 \text{ce}_{0.114}(z, 0.16), \quad (3)$$

where  $z = \omega t$ . Since  $\beta = 0.114 = 57/500$ , by § 4.71 the period of (2), (3) is  $1000\pi$ .

**15.14. Interpretation of (2) § 15.13.**  $\cos 0.114z$  is the dominant term, and as the coefficients of the other terms are comparatively small, these terms may be considered to represent ripples of pulsance  $> 0.114\omega$ . The motion of the coil is illustrated by the heavy curve of Fig. 22. The coil reaches the position  $\xi = 0$  after a time

FIG. 22. Curve showing displacement of L.S. coil outside magnet.

lapse of approximately the first quarter period of  $\cos 0.114\omega t$ , i.e.  $\tau = \pi/0.228\omega$ . If the pulsance of the coil current were  $\omega = 35\pi$ ,  $\tau \simeq 1/8$  second. Since we assumed absence of constraint and loss, if we make the additional assumption that the magnetic field is zero when  $\xi < 0$ , the coil having reached  $\xi = 0$  will move onwards by virtue of its momentum. The time taken for the coil to travel the distance  $\xi = \xi_0$  may be increased by reducing  $q$  [201].

**15.15. Electro-mechanical rectification.** The effect described above has been called by this name because a sinusoidal current in the coil causes a unidirectional motion. If, however, the magnetic field were negative behind the origin—antisymmetrical about 0—the coil would oscillate about 0, so the question of rectification would not arise.

Attention is drawn to the following features:

- (a) In (2) § 15.13 there is no term of pulsance equal to that of the current,  $2\omega$ .

- (b) On the dominant component  $\cos 0.114\omega t$  is superimposed an infinite number of ripples of different pulsataces, which are non-integral multiples of  $0.114\omega$ .

**15.16. Parametric point in unstable region of Fig. 8.** The solution in § 15.12 pertains to a stable region. If  $(a, q)$  lies in an unstable region the form of solution is given at (1) or (3), 2° § 4.70. This entails the rate of oscillation of the coil being the same as the frequency of the current, while  $\xi_{\max}$  increases with increase in time. The reader may find it of interest to investigate the unstable case with and without damping.

**15.17. Pulsatance multiplication.** In Fig. 11 each iso- $\beta$  curve (if continued far enough) intersects the  $q$ -axis. Between the intersections of  $a_0, b_1$  with this axis,  $0 < \beta < 1$ ,  $a = 0$ , and each  $\beta$  corresponds to a different pulsatance of the dominant term in (2) § 15.13. Hence in this range, by varying  $q$  we may obtain any pulsatance in the range  $0 < \beta\omega < \omega$ . When the point is in any other stable region ( $q > 0$ ) the dominant term will not always have the lowest pulsatance, e.g. in (2) § 5.310 the dominant term has a pulsatance about four times that of the first term. Thus in a system satisfying (4) § 15.11, by varying the driving force (proportional to  $q$ ) and/or the constraint (proportional to  $a$ ), the pulsatance of the dominant component may be any multiple or sub-multiple of  $2\omega$ , the pulsatance of the driving force.

**15.20. Frequency modulation.** In radio telephony, e.g. broadcasting, a wave train of constant frequency and amplitude is radiated from the aerial at the transmitting station during intervals. This is called the 'carrier' wave. The process at the transmitter whereby this wave is made to 'carry' signals, which become audible at the receiver, is known as *modulation*, i.e. the signal characters modulate the carrier wave. In the receiver there is a circuit arrangement for demodulating the radio frequency, thereby reproducing the original signals, usually rendered audible by a loud-speaker. There are three types of modulation, (a) frequency, (b) amplitude, (c) phase. We shall deal with (a), where it is implied that signals cause a variation in the frequency of the radio oscillations at the transmitter. The same principle is used in the case of the audio warble tone employed in acoustical test rooms to reduce standing wave effect. Instead of using a constant test frequency, the latter undergoes cyclic

variation covering a band of 50 cycles per second or more,† at a rate which may be altered.

**15.21. Classification.** Frequency modulation may be classified under three heads: 1°. Direct capacitance modulation; 2°. Exact frequency modulation; 3°. Inverse capacitance modulation [2].

1°. *Direct capacitance modulation.* Consider the loss-free circuit shown schematically in Fig. 23 A. Inductance  $L$  is in series with

FIG. 23. (A) Schematic of loss-free electrical circuit with periodically variable capacitance.

(B) Illustrating frequency modulation *without* amplitude modulation.

(C) Illustrating capacitance type microphone.

(D) As at (A) but with resistance  $R$  in circuit.

capacitance  $C$ , which varies with time, so we write  $C = C(t)$ , a function of  $t$ . We assume that in practice the loss in  $L$ ,  $C$ , and the connecting wires would be neutralized by the negative resistance effect of a thermionic valve. If  $Q$  denotes the quantity of electricity in the capacitance, the circuital differential equation is

$$\frac{d^2 Q}{dt^2} + \frac{Q}{LC(t)} = 0. \quad (1)$$

We shall assume that  $C(t) = C_0(1 + \epsilon \cos 2\omega_1 t)$ ,  $C_0$  being constant and  $\epsilon \ll 1$ . If  $\epsilon = 0$ , the central or carrier pulsance of the circuit is  $\omega_0 = 1/(LC_0)^{\frac{1}{2}}$ . As  $C(t)$  alters from  $C_0(1 - \epsilon)$  to  $C_0(1 + \epsilon)$  and back again periodically, the pulsance varies over the range  $1/[LC_0(1 - \epsilon)]^{\frac{1}{2}}$  to  $1/[LC_0(1 + \epsilon)]^{\frac{1}{2}}$ , and the central or carrier wave is said to be frequency modulated. A frequency modulated wave is illustrated in Fig. 23 B.

† Usually a percentage of the central or test frequency.

Using the binomial expansion of  $(1 + \epsilon \cos 2\omega_1 t)^{-1}$ , (1) takes the form

$$\frac{d^2 Q}{dt^2} + \omega_0^2 (1 - \epsilon \cos 2\omega_1 t + \epsilon^2 \cos^2 2\omega_1 t - \epsilon^3 \cos^3 2\omega_1 t + \dots) Q = 0. \quad (2)$$

If we write  $z = \omega_1 t$ , expand the circular functions, and put  $\theta_0 = (\omega_0/\omega_1)^2 [1 + \frac{1}{2}\epsilon^2 + \dots]$ ,  $2\theta_2 = -(\omega_0/\omega_1)^2 [\epsilon + \frac{3}{4}\epsilon^3 + \dots]$ , etc., (2) becomes

$$\frac{d^2 Q}{dz^2} + \left( \theta_0 + 2 \sum_{r=1}^{\infty} \theta_{2r} \cos 2rz \right) Q = 0, \quad (3)$$

which is Hill's equation, whose solution is treated in § 6.11 et seq., and § 15.25.

Since the extreme values of  $C(t)$  are  $C_0'(1 \pm \epsilon)$ , we have

$$\omega_{\max}^2 = 1/LC_0(1 - \epsilon),$$

so  $\omega_{\max} \simeq \omega_0(1 + \frac{1}{2}\epsilon)$ : also  $\omega_{\min} \simeq \omega_0(1 - \frac{1}{2}\epsilon)$ . Thus the pulsance variation on either side of  $\omega_0$  is approximately

$$\frac{1}{2}(\omega_{\max} - \omega_{\min}) = \Delta\omega = \frac{1}{2}\omega_0\epsilon,$$

so  $\epsilon = 2\Delta\omega/\omega_0$ . Substituting this in (2) and omitting terms in  $\epsilon^2, \epsilon^3, \dots$ , as a first approximation we obtain

$$\frac{d^2 Q}{dt^2} + (\omega_0^2 - 2\omega_0 \Delta\omega \cos 2\omega_1 t) Q = 0. \quad (4)$$

Writing  $z = \omega_1 t$ ,  $Q = y$  in (4) leads to the canonical form

$$\frac{d^2 y}{dz^2} + (a - 2q \cos 2z)y = 0, \quad (5)$$

with  $a = (\omega_0/\omega_1)^2$ ,  $q = \omega_0 \Delta\omega/\omega_1^2$ . The solution is in § 15.26. If  $C$  were fixed and  $L$  varied cyclically, an equation similar to (5) would be obtained.

2°. *Exact frequency modulation.* This is a mathematical concept, and so far as the analysis is concerned, we need not consider the method by which the desired practical result is obtained. The differential equation takes the form

$$\frac{d^2 Q}{dt^2} + \psi(t) Q = 0, \quad (1)$$

where  $\psi(t)$  is a periodic continuous or piecewise continuous function of  $t$ . If  $[\psi(t)]^\dagger = \omega_0 - \Delta\omega \cos 2\omega_1 t$ , the pulsance varies from

$(\omega_0 + \Delta\omega)$  to  $(\omega_0 - \Delta\omega)$  *exactly*, and not approximately as in 1°. Substituting this value of  $\psi(t)$  in (1) leads to

$$\frac{d^2 Q}{dt^2} + (\omega_0^2 + \frac{1}{2}\Delta^2\omega - 2\omega_0\Delta\omega \cos 2\omega_1 t + \frac{1}{2}\Delta^2\omega \cos 4\omega_1 t)Q = 0, \quad (2)$$

which is a form of extended Mathieu equation, with

$$\theta_0 = (\omega_0^2 + \frac{1}{2}\Delta^2\omega)/\omega_1^2, \quad \theta_2 = -2\omega_0\Delta\omega/\omega_1^2, \quad \theta_4 = \frac{1}{2}\Delta^2\omega/\omega_1^2,$$

$\theta_6 = \theta_8 = \dots = 0$ ,  $z = \omega_1 t$ . If  $\Delta\omega$  is small enough, the terms in  $\Delta^2\omega$  may be neglected and (2) is then identical with (4) § 1°. Otherwise the equation must be solved without this reduction.

3°. *Inverse capacitance modulation.* An example of this class is found in a certain type of condenser microphone shown schematically in Fig. 23 c. Assuming that a sound wave of pulsance  $\omega_1$  impinges on the diaphragm, the capacitance of the microphone varies *inversely* as the distance  $d = d_0(1 - \epsilon \cos 2\omega_1 t)$  from the back-plate. Then the capacitance at any instant is given by  $C(t) = K/d_0(1 - \epsilon \cos 2\omega_1 t)$ , where  $d_0$  is the separation between the diaphragm and back-plate in quiescent intervals, and  $K$  is a constant for the microphone. By (1) § 1° the differential equation for the system is, with  $C_0 = K/d_0$ ,

$$\frac{d^2 Q}{dt^2} + \frac{Q}{LC_0}(1 - \epsilon \cos 2\omega_1 t) = 0, \quad (1)$$

$$\text{or} \quad \frac{d^2 Q}{dt^2} + \omega_0^2(1 - \epsilon \cos 2\omega_1 t)Q = 0, \quad (2)$$

where  $\omega_0^2 = 1/LC_0$ . The nomenclature 'inverse capacitance modulation' is due to  $(1 - \epsilon \cos 2\omega_1 t)$  being in the numerator in (1), whereas in (1) § 1° it is in the denominator.

**15.22. Modulation zones.** The differential equation for the three classes of modulation considered in § 15.21 may for present purposes be expressed in the form

$$\frac{d^2 y}{dz^2} + a(1 - 2\gamma \cos 2z)y = 0, \quad (1)$$

where  $z = \omega_1 t$ ,  $2\omega_1$  being the modulating or signal pulsance;  $a = (\omega_0/\omega_1)^2$ ,  $\omega_0$  being the central or carrier pulsance which is modulated;  $\gamma = \Delta\omega/\omega_0$ ,  $\Delta\omega$  being the deviation on either side of  $\omega_0$ .  $2\omega_1$  is the rate at which the deviation occurs. Equation (1) may be used for 1°, 2°, § 15.21 provided the requisite approximation is permissible.

Referring to the stability chart Fig. 8, it is expedient for present purposes to use that half where  $q \geq 0$ , and to interchange the  $a, q$

FIG. 24. Stability chart for frequency modulation [2].

FIG. 25. Modulation zones in Fig. 24 [2].

axes. Then we have the diagram Fig. 24, and by giving  $\gamma$  a series of values, the lines  $q = a\gamma$  may be inserted as shown.

It is convenient to divide Fig. 24 into three zones as illustrated in Fig. 25. Zone 1, covering the range  $0.1 \leq \gamma < 0.5$ , is of theoretical interest only.  $2\Delta\omega$  approaches to  $\omega_0$ , and  $2\omega_1$  to  $\omega_0$ . The line  $\gamma = 0.5$

may be regarded as a boundary, since in practice  $\gamma < 0.5$ , in fact it is usually much less than 0.5. The second zone includes the audio warble tone and covers the range  $2 \times 10^2 \leq a \leq 2.4 \times 10^6$ , with  $0 < \gamma \leq 0.1$ ,  $\Delta\omega < \omega_0$ ,  $\omega_1 \ll \omega_0$ . Zone 3 covers the range of frequency modulation in radio transmission, where  $9 \times 10^5 \leq a \leq 1.2 \times 10^{13}$ ,  $0 < \gamma \leq 0.025$ ,  $\Delta\omega \ll \omega_0$ ,  $\omega_1 \ll \omega_0$ . For a given value of  $\omega_0$ , since  $\gamma = \Delta\omega/\omega_0$ , any of the straight lines in Fig. 24 represents a condition of constant pulsance deviation.  $2\gamma$  may be regarded as the modulation coefficient; the signal strength is proportional thereto.

**15.23. Stability of oscillations.** Consider the circuit of Fig. 23A in conjunction with the line  $\gamma = 0.025$  in Figs. 24, 25. Imagine the circuit parameters to be continuously variable so that as  $\omega_0 = 1/(LC_0)^{\frac{1}{2}}$  increases, the ratio  $(\omega_0/\omega_1)^2 = a$  does likewise, but  $\gamma$ , the fractional deviation, remains constant at 0.025. Commencing at  $a = 0$ , the line  $\gamma = 0.025$  intersects the  $(a, q)$  curves where they are close to each other, and as  $a$  increases, the intercepts in the stable regions steadily increase, while those in the unstable regions decrease. As a rough approximation the intersections occur when  $a = m^2$ ,  $m$  a positive integer. With  $a > 10^6$ , the probability of instability in a radio circuit, whose parameters are chosen at random, is small. Moreover, if  $a$  is large enough, the operating point  $(a, q)$  will probably lie in a stable region between two characteristics for Mathieu functions of integral order.

This statement is based on the assumption that changes in  $a = (\omega_0/\omega_1)^2$  are likely to be small. The curves  $a_{1000}$ ,  $b_{1001}$  cross the  $a$ -axis at  $a = 10^6$  and  $a = (10^3 + 1)^2 = 10^6 + 2001$ , respectively. Thus when  $q$  is small and positive, if we select a point midway between  $a_{1000}$ ,  $b_{1001}$ , the permissible variation in pulsance ratio  $a^{\frac{1}{2}} = \omega_0/\omega_1$ , to avoid encroaching upon an unstable region would be less than 1 part in 2,000. When  $q > 0$  exceeds a certain value the two characteristics begin to approach each other rapidly, and the permissible variation in  $(\omega_0/\omega_1)$  to avoid instability then decreases with increase in  $q$ . In precision work, where thermostatic control and temperature-compensated components are used, the pulsance variation of an oscillator would be very small.

The greater  $\gamma$ , e.g. 0.5, the wider the intercept in an unstable region and the higher the probability of unstable operation. It is clear, therefore, that to ensure stable operation over a wide range

of  $a$ , and consequently of the signal pulsance  $2\omega_1\gamma = \Delta\omega/\omega_0$  should be small compared with  $1/2$ .

**15.24. The line spectrum in radio frequency modulation [21].** We have mentioned that in this case  $a$  is very large. If  $\gamma \ll 1$ , then  $a \gg 2a\gamma = 2q > 0$ , and the condition for validity of (13) § 4.80 is fulfilled. Apart from a constant multiplier, this series represents  $Q$ , the quantity of electricity in the electrical circuit Fig. 23 A. Thus writing  $Q$  for  $y$ , and  $\omega_1 t$  for  $z$  in (1), (13) § 4.80, we obtain the current

$$I = \frac{dQ}{dt} = -\omega_1 \sum_{r=-r_0}^{r_0} C_r J_r(q/2a^\dagger) \sin[(a^\dagger - 2r)\omega_1 t - \alpha], \quad (1)$$

where  $C_r = C(a^\dagger - 2r) \simeq Ca^\dagger$ , since in § 4.80,  $a^\dagger \gg r_0$ . Now  $q = a\gamma$ ,  $a = (\omega_0/\omega_1)^2$ ,  $\gamma = \Delta\omega/\omega_0$ , so (1) may be written

$$I \simeq -\omega_0 C \sum_{r=-r_0}^{r_0} J_r(\Delta\omega/2\omega_1) \sin[(\omega_0 - 2r\omega_1)t - \alpha]. \quad (2)$$

Taking  $\Delta\omega/2\omega_1 = h$ ,  $J_{-r} = (-1)^r J_r$ , (2) may be set out in the form

<i>Discrete components</i>	<i>Pulsances</i>										
$-I/\omega_0 C =$ $J_0(h) \sin(\omega_0 t - \alpha) +$ $+ J_1(h) \{ \sin[(\omega_0 - 2\omega_1)t - \alpha] - \sin[(\omega_0 + 2\omega_1)t - \alpha] \} +$ $+ J_2(h) \{ \sin[(\omega_0 - 4\omega_1)t - \alpha] + \sin[(\omega_0 + 4\omega_1)t - \alpha] \} +$ $+ \dots +$ $+ J_{r_0}(h) \{ \sin[(\omega_0 - 2r_0\omega_1)t - \alpha] \pm \sin[(\omega_0 + 2r_0\omega_1)t - \alpha] \}$	<table style="width: 100%; border-collapse: collapse;"> <tr> <td style="text-align: center;"><math>\omega_0</math>,</td> <td style="text-align: left;">the carrier</td> </tr> <tr> <td style="text-align: center;"><math>\omega_0 - 2\omega_1</math>,</td> <td style="text-align: left;"><math>\omega_0 + 2\omega_1</math></td> </tr> <tr> <td style="text-align: center;"><math>\omega_0 - 4\omega_1</math>,</td> <td style="text-align: left;"><math>\omega_0 + 4\omega_1</math></td> </tr> <tr> <td style="text-align: center;"><math>\dots</math></td> <td style="text-align: left;"><math>\dots</math></td> </tr> <tr> <td style="text-align: center;"><math>\omega_0 - 2r_0\omega_1</math>,</td> <td style="text-align: left;"><math>\omega_0 + 2r_0\omega_1</math></td> </tr> </table>	$\omega_0$ ,	the carrier	$\omega_0 - 2\omega_1$ ,	$\omega_0 + 2\omega_1$	$\omega_0 - 4\omega_1$ ,	$\omega_0 + 4\omega_1$	$\dots$	$\dots$	$\omega_0 - 2r_0\omega_1$ ,	$\omega_0 + 2r_0\omega_1$
$\omega_0$ ,	the carrier										
$\omega_0 - 2\omega_1$ ,	$\omega_0 + 2\omega_1$										
$\omega_0 - 4\omega_1$ ,	$\omega_0 + 4\omega_1$										
$\dots$	$\dots$										
$\omega_0 - 2r_0\omega_1$ ,	$\omega_0 + 2r_0\omega_1$										

(3)

It follows from (3) that when the carrier of pulsance  $\omega_0$  is modulated by an oscillation of pulsance  $2\omega_1 \ll \omega_0$ , there results a line spectrum or series of discrete pulsance components. These are spaced at equal intervals  $2\omega_1$  on each side of the carrier or central oscillation of pulsance  $\omega_0$ , as illustrated in Fig. 26. The amplitude of the component of pulsance  $(\omega_0 \pm 2r\omega_1)$  is proportional to the  $J$ -Bessel function of order  $r$ , namely,  $J_r(\Delta\omega/2\omega_1)$ . In Fig. 26,  $\Delta\omega/2\omega_1 = 0.1$ . When  $> 1$ , the amplitudes of some components may exceed that of the carrier, as will be seen from tables of  $J_r(u)$ .

**15.25. Approximate stable solution of (1) 1° § 15.21.** The equation may be written

$$Q'' + a\rho^2 Q = 0, \quad (1)$$

with  $a = \omega_0^2 = 1/LC_0$ ,  $\rho = (1 + \epsilon \cos 2\omega_1 t)^{-1/2}$ . If the conditions  $a \gg 1$ ,

$0 < \epsilon < 1$  are satisfied, then by (13) § 4.82 an approximate stable solution is

$$Q_1(t) = A(1 + \epsilon \cos 2\omega_1 t)^{\frac{1}{2}} \cos \left[ \omega_0 \sqrt{\frac{1}{2}} \int_0^t dt / (1 + \epsilon \cos 2\omega_1 t)^{\frac{1}{2}} \right] \quad (2)$$

$$= A(1 + \epsilon \cos 2\omega_1 t) \cos \left[ \{\omega_0 / (1 + \epsilon)\} \int_0^t dt / (1 - \lambda^2 \sin^2 \omega_1 t)^{\frac{1}{2}} \right], \quad (3)$$

FIG. 26. Illustrating relative amplitudes of side bands in frequency modulation due to a single modulating wave.

with  $\lambda^2 = 2\epsilon/(1 + \epsilon)$ ,  $A$  being an arbitrary constant, the second one not being needed here. Thus, with  $\omega_0/\omega_1 = \bar{\omega}_0$ ,

$$Q_1(t) = A(1 + \epsilon \cos 2\omega_1 t)^{\frac{1}{2}} \cos[\{\bar{\omega}_0 / (1 + \epsilon)\} F(\lambda, \omega_1 t)], \quad (4)$$

where  $F$  is an incomplete elliptic integral of the first kind with modulus  $\lambda$ , i.e. the integral part in (3).

The type of function represented by (4) is depicted in Fig. 10A. Both amplitude and frequency modulation are exhibited. The former is associated with the factor  $(1 + \epsilon \cos 2\omega_1 t)^{\frac{1}{2}}$ , and the latter with  $F(\lambda, \omega_1 t)$ . These expressions are periodic in  $t$ , with period  $\pi/\omega_1$ . The ratio max./min. amplitude for  $\epsilon = 0.75$  is  $[(1 + 0.75)/(1 - 0.75)]^{\frac{1}{2}} = 1.63/1$ . This is an extreme case and corresponds to  $\gamma = 0.375$  (see

Fig. 25). If  $\epsilon$  were 0.02 for radio frequency modulation, the amplitude ratio would be 1.01, i.e. 1 per cent. amplitude modulation.

By (2) above and (16) § 4.82 the 'instantaneous frequency' is

$$f(t) = \frac{d}{dt} \left[ \frac{\omega_0}{2\pi} \int_0^t dt / (1 + \epsilon \cos 2\omega_1 t)^{\frac{1}{2}} \right] = (\omega_0/2\pi) / (1 + \epsilon \cos 2\omega_1 t)^{\frac{1}{2}}. \quad (5)$$

If  $\epsilon = 0.5$  the max. and min. frequencies are approximately  $1.41f_0$  and  $0.82f_0$ , with  $f_0 = \omega_0/2\pi$ . Thus the variation is asymmetrical about  $f_0$ . For  $\epsilon = 0.02$  the values are nearly  $(1 \pm 0.01)f_0$ , so if  $f_0$  were 10 megacycles per second, the frequency would vary  $10^5$  cycles per second on each side of the carrier, at a rate  $\omega_1/\pi$  c.p.s.

The number of oscillations in one period of the modulating frequency  $\omega_1/\pi$  is the integral of the 'instantaneous frequency' over the period. Thus by (5)

$$N = \frac{\omega_0}{2\pi} \int_0^{\pi/\omega_1} dt / (1 + \epsilon \cos 2\omega_1 t)^{\frac{1}{2}} = \frac{\omega_0}{2\pi(1+\epsilon)^{\frac{1}{2}}} \int_0^{\pi/\omega_1} dt / (1 - \lambda^2 \sin^2 \omega_1 t)^{\frac{1}{2}}. \quad (6)$$

Writing  $\omega_1 t = \tau$ , (6) becomes

$$N = \frac{(\omega_0/\omega_1)}{\pi(1+\epsilon)^{\frac{1}{2}}} \int_0^{\pi} d\tau / (1 - \lambda^2 \sin^2 \tau)^{\frac{1}{2}} = \frac{(\omega_0/\omega_1)}{\pi(1+\epsilon)^{\frac{1}{2}}} F(\lambda, \frac{1}{2}\pi). \quad (7)$$

Taking  $\omega_0 = 2\pi \times 10^7$ ,  $\omega_1 = 2\pi \times 10^3$ , by (7) the oscillations per period  $\omega_1/\pi$  are

$$N = \frac{10^4}{\pi \times 1.01} \times 1.5874 \simeq 5000. \quad (8)$$

*Current corresponding to (4).* Since  $I_1(t) = \frac{d}{dt} Q_1(t)$ , differentiation of (4) leads to

$$I_1(t) = - \frac{A}{(1 + \epsilon \cos 2\omega_1 t)^{\frac{1}{2}}} \left[ \frac{\omega_0}{(1 + \epsilon)^{\frac{1}{2}}} \sin \left\{ \frac{\bar{\omega}_0}{(1 + \epsilon)^{\frac{1}{2}}} F(\lambda, \omega_1 t) \right\} + \right. \\ \left. + \frac{\epsilon \omega_1 \sin 2\omega_1 t}{2(1 + \epsilon \cos 2\omega_1 t)^{\frac{1}{2}}} \cos \left\{ \frac{\bar{\omega}_0}{(1 + \epsilon)^{\frac{1}{2}}} F(\lambda, \omega_1 t) \right\} \right]. \quad (9)$$

The type of function represented by (9) is illustrated in Fig. 10 B. When  $\omega_0 \gg \omega_1$ , and  $\epsilon$  is such that the second term in [ ] may be neglected in comparison with the first,  $I_1(t)_{\max}$  occurs approximately at the same  $t$  as  $Q_1(t)_{\min}$  (see Figs. 10 A, B).

**15.26. Approximate solution of (4) 1° § 15.21.** Referring to (1) § 15.25, we now take  $\rho^2 = [1 - (2\Delta\omega/\omega_0)\cos 2\omega_1 t]$ . Writing

$$\epsilon = \frac{2\Delta\omega}{\omega_0},$$

the solution is

$$Q_1(t) = [B/(1 - \epsilon \cos 2\omega_1 t)^{\frac{1}{2}}] \cos \left[ \omega_0 \int_0^t (1 - \epsilon \cos 2\omega_1 t)^{\frac{1}{2}} dt \right]. \quad (1)$$

Now

$$\int_0^t (1 - \epsilon \cos 2\omega_1 t)^{\frac{1}{2}} dt = (1 + \epsilon)^{\frac{1}{2}} \int_0^t (1 - \lambda^2 \cos^2 \omega_1 t)^{\frac{1}{2}} dt = \frac{E_1(\lambda, \omega_1 t)}{\omega_1(1 + \epsilon)^{-\frac{1}{2}}},$$

where  $E_1$  is an incomplete elliptic integral defined at (14) § 4.82, with  $\lambda^2 = 2\epsilon/(1 + \epsilon)$ . Thus

$$Q_1(t) = [B/(1 - \epsilon \cos 2\omega_1 t)^{\frac{1}{2}}] \cos[\bar{\omega}_0(1 + \epsilon)^{\frac{1}{2}} E_1(\lambda, \omega_1 t)], \quad (2)$$

$B$  being an arbitrary constant, the second one not being required here.

The 'instantaneous frequency' is given by

$$f(t) = (\omega_0/2\pi)(1 - \epsilon \cos 2\omega_1 t)^{\frac{1}{2}}, \quad (3)$$

and

$$N = \frac{1}{\pi}(\omega_0/\omega_1)(1 + \epsilon)^{\frac{1}{2}} E(\lambda, \frac{1}{2}\pi). \quad (4)$$

**15.30. Circuit having resistance.** Hitherto we have discussed resistanceless circuits, the differential equation having the form at (1), 1° § 15.21. Suppose that a constant resistance  $R$  is included in circuit, as shown schematically in Fig. 23 D. The p.d. across  $R$  is  $RI = R dQ/dt$ , so the equation for this case is

$$\frac{d^2 Q}{dt^2} + \frac{R}{L} \frac{dQ}{dt} + \frac{Q}{LC(t)} = 0. \quad (1)$$

If  $\epsilon$  is small enough, we may take  $1/C(t) \simeq (1 - \epsilon \cos 2\omega_1 t)/C_0$ , and (1) becomes

$$\frac{d^2 Q}{dt^2} + \frac{R}{L} \frac{dQ}{dt} + \frac{Q}{LC_0}(1 - \epsilon \cos 2\omega_1 t) = 0. \quad (2)$$

Writing  $Q = y$ ,  $1/LC_0 = \omega_0^2$ ,  $z = \omega_1 t$ ,  $R/\omega_1 L = 2\kappa$ ,  $\bar{a} = (\omega_0/\omega_1)^2$ ,  $2q = \bar{a}\epsilon$ , (2) takes the form

$$y'' + 2\kappa y' + (\bar{a} - 2q \cos 2z)y = 0. \quad (3)$$

The solution of equations of this type is treated in §§ 4.83–4.86, 5.60, and stability conditions are given in § 4.83. An unstable oscillatory

circuit† may be stabilized by adjusting  $R$  to some suitable value depending upon the other parameters. Moreover, as shown in § 4.84, the stable regions for (3) cover a greater area than those if  $\kappa = 0$ . They increase in extent with increase in  $R$  and, therefore,  $\kappa$ . When the point  $(\bar{a}, q)$  is on a characteristic curve for equation (3),  $\kappa = \mu$  in § 4.84, and the motion is periodic, i.e. a neutral condition. Once started, the oscillation would (in theory) continue unaltered. In practice, however, it would usually either decay to zero or increase until its growth was arrested by the natural limitations of the system.

If  $(\bar{a}, q)$  lies in a  $\left. \begin{array}{l} \text{stable} \\ \text{unstable} \end{array} \right\}$  region of Fig. 11, ‡  $\left. \begin{array}{l} \kappa > \mu \\ \mu > \kappa \end{array} \right\}$  and the oscillation  $\left. \begin{array}{l} \rightarrow 0 \\ \rightarrow \pm\infty \end{array} \right\}$  as  $t \rightarrow +\infty$ .

**15.31. Approximate stable solution of (1) § 15.30.** Substitute  $Q = ve^{-\kappa t}$ , with  $R/L = 2\kappa$ , and we get

$$\frac{d^2v}{dt^2} + (a\rho^2 - \kappa^2)v = 0, \quad (1)$$

where  $a = \omega_0^2 = 1/LC_0$ ,  $\rho^2 = 1/(1 + \epsilon \cos 2\omega_1 t)$ . Now write  $(a\rho^2 - \kappa^2) = a\varphi^2$ , with  $\varphi^2 = (\rho^2 - \kappa^2/a)$ , and (1) becomes

$$\frac{d^2v}{dt^2} + a\varphi^2v = 0. \quad (2)$$

If  $a \gg 1$ ,  $0 < \epsilon < 1$ ,  $\kappa^2/a \ll 1$ , by (13) § 4.82 an approximate stable solution of (2) is

$$v_1(t) = B\varphi^{-\frac{1}{2}} \cos \left[ \omega_0 \int_0^t \varphi dt \right], \quad (3)$$

$B$  being an arbitrary constant. But

$$\varphi = (1 + \epsilon \cos 2\omega_1 t)^{-\frac{1}{2}} [1 - (\kappa^2/a)(1 + \epsilon \cos 2\omega_1 t)]^{\frac{1}{2}} \quad (4)$$

$$\simeq (1 + \epsilon \cos 2\omega_1 t)^{-\frac{1}{2}} - (\kappa^2/2a)(1 + \epsilon \cos 2\omega_1 t)^{\frac{1}{2}}, \quad (5)$$

and by (4)

$$\varphi^{\frac{1}{2}} \simeq (1 + \epsilon \cos 2\omega_1 t)^{-\frac{1}{4}} [1 - (\kappa^2/4a)(1 + \epsilon \cos 2\omega_1 t)]; \quad (6)$$

$$\text{also} \quad (1 + \epsilon \cos 2\omega_1 t)^{\frac{1}{2}} = (1 + \epsilon)^{\frac{1}{2}} (1 - \lambda^2 \sin^2 \omega_1 t)^{\frac{1}{2}} \quad (7)$$

† It is tacitly implied in such circuits that a thermionic valve is incorporated, so that a negative resistance effect may be obtained.

‡ Reference is made here to the stability diagram for (3). The boundary lines are  $\mu = \kappa$ .

with  $\lambda^2 = 2\epsilon/(1+\epsilon)$ . Hence from (3)–(7), on substituting  $Q_1 = v_1 e^{-\kappa t}$ , we obtain

$$Q_1(t) \simeq \frac{Be^{-\kappa t}(1+\epsilon \cos 2\omega_1 t)^{\frac{1}{2}}}{[1-(\kappa^2/4a)(1+\epsilon \cos 2\omega_1 t)]} \cos \left\{ \bar{\omega}_0 \left[ \frac{F(\lambda, \omega_1 t)}{(1+\epsilon)^{\frac{1}{2}}} - \frac{\kappa^2 E(\lambda, \omega_1 t)}{2a(1+\epsilon)^{-\frac{1}{2}}} \right] \right\}. \quad (8)$$

The type of function represented by (8) is that of Fig. 10A but having an exponential decay, i.e. the influence of  $R$  is to cause extinction of the oscillation, unless a negative resistance effect were introduced to counteract it.

**15.32. Circuit with periodically varying resistance.** By (1) § 15.30, the equation for the free oscillations is

$$\frac{d^2 Q}{dt^2} + \frac{R}{L} \frac{dQ}{dt} + \frac{Q}{LC} = 0, \quad (1)$$

where  $L$ ,  $C$  are constant, but  $R = R_0 + R_1 \varphi(\omega_1 t)$ ,  $\varphi$  having period  $2\pi/\omega_1$ , mean value zero,  $|\varphi| \leq 1$ .

Write  $Q = e^{-\kappa(t)} u(t)$ , with  $\kappa(t) = \frac{1}{2L} \int_0^t R(\tau) d\tau$ , then (1) becomes

$$u'' + \left( \frac{1}{LC} - \frac{R^2}{4L^2} - \frac{R'}{2L} \right) u = 0. \quad (2)$$

Now  $R^2 = R_0^2 + 2R_0 R_1 \varphi + R_1^2 \varphi^2$ ,  $R' = dR/dt = \omega_1 R_1 \varphi'$ , and if we put  $\kappa_0 = R_0/2L$ ,  $\kappa_1 = R_1/2L$ ,  $\omega_0^2 = (1/LC) - (R_0^2/4L^2) = a$ , we obtain

$$\left( \frac{1}{LC} - \frac{R^2}{4L^2} - \frac{R'}{2L} \right) = \omega_0^2 - \kappa_1 [2\kappa_0 \varphi + \kappa_1 \varphi^2 + \omega_1 \varphi'] \quad (3)$$

$$= a - 2q \psi(\omega_1 t). \quad (4)$$

Thus from (2), (4)

$$u'' + [a - 2q \psi(\omega_1 t)] u = 0, \quad (5)$$

which is a standard form of Hill's equation, whose solution may be obtained by the procedure in Chapter VI.

If we commence with the circuital equation

$$L \frac{dI}{dt} + RI + \frac{1}{C} \int I dt = 0 \quad (6)$$

and write  $I = e^{-\kappa(t)} w(t)$ , we obtain

$$w'' + \left( \frac{1}{LC} - \frac{R^2}{4L^2} + \frac{R'}{2L} \right) w = 0, \quad (7)$$

which is identical in form with (2) except for the sign of  $R'/2L$ . Then (7) may be written

$$w'' + [a - 2q\psi_1(\omega_1 t)]w = 0, \quad (8)$$

where  $2q\psi_1(\omega_1 t) = \kappa_1\{2\kappa_0\varphi + \kappa_1\varphi^2 - \omega_1\varphi'\}$ .

If a driving e.m.f.  $E(t)$  is injected into the circuit, the coupling with the generator being negligible, the circuital differential equation is

$$L \frac{dI}{dt} + RI + \frac{1}{C} \int I dt = E(t). \quad (9)$$

Then with the above substitution we get

$$w'' + [a - 2q\psi_1(\omega_1 t)]w = (e^{\kappa_0 t}/L)(dE/dt), \quad (10)$$

which may be solved by aid of Chapter VI.

These equations occur in the theory of the super-regenerative radio receiver, and reference [45] should be consulted for further details which are too extensive for inclusion here.

**15.40. Dynamical system satisfying Mathieu's equation.** A simple link-mass-spring mechanism is shown schematically in Fig. 5A. The mass  $m$  slides over a frictionless horizontal plane, along the straight line  $CA$ . The links are massless and the pin-joints at  $A$ ,  $O$ ,  $B$  are frictionless. Also the spring is massless and unstressed when  $m$  is at  $D$ , while  $AB$ ,  $OA$  are long enough for motion parallel to  $BD$  to be negligible in comparison with that along the axis of the spring.

The driving force  $F_0 = lf_0 \cos 2\omega t$  is applied to the cross-head  $B$ . It may be resolved into two components, one along  $AB$ , the other along  $DA$ . The latter is nearly  $(f_0 \cos 2\omega t)y$ , and it causes  $m$  to slide along the line  $CDA$ . Three forces are to be considered in connexion with  $m$ , namely, (1) the inertia  $m d^2y/dt^2$ , (2) the constraint  $sy$  due to the spring, (3) the driving force  $(f_0 \cos 2\omega t)y$ . Then the equation of motion is

$$m \frac{d^2y}{dt^2} + sy = (f_0 \cos 2\omega t)y. \quad (1)$$

Substituting  $z = \omega t$ ,  $a = s/\omega^2 m$ ,  $2q = f_0/\omega^2 m$ , we obtain the standard form

$$\frac{d^2y}{dz^2} + (a - 2q \cos 2z)y = 0. \quad (2)$$

If we write  $q = a\gamma$ , where  $\gamma = f_0/2s$ , (2) becomes

$$y'' + a(1 - 2\gamma \cos 2z)y = 0. \quad (3)$$

**15.41. Behaviour of system in § 15.40.** Draw a line  $a = q/\gamma$  in Fig. 27. Since  $a = s/\omega^2 m$ ,  $\omega$  will be large at points on the line near the origin, but will decrease gradually in passing along the positive direction. When  $\omega$  is such that the line intersects one of the curves  $b_m$ ,  $a_m$ , e.g. the points 1–8, the motion of  $m$  is periodic and neutral.

FIG. 27. Stability diagram for mechanism in Fig. 5 A.

Otherwise it is either stable or unstable according to the region in which the point  $(a, q)$  lies. The remarks in § 15.17 on variation of pulsance apply in the present case when  $(a, q)$  lies within or on a border-line of a stable region. For a component of given pulsance to have an amplitude greater than that of any other,  $(a, q)$  must be suitably selected. For instance, suppose the motion includes the first sub-harmonic of the driving force. Since all Mathieu functions of odd integral order, namely,  $ce_{2n+1}(\omega t, q)$  and  $se_{2n+1}(\omega t, q)$ , have a sub-harmonic of pulsance  $\omega$ , the values of  $a, q$  at the intersections of the respective curves  $a_{2n+1}$ ,  $b_{2n+1}$ , and the line  $a = q/\gamma$  fulfil the required condition. For predominance of the sub-harmonic we consider the relative magnitudes of the coefficients  $A, B$  in the series

for  $ce_{2n+1}$ ,  $se_{2n+1}$ ,  $n = 0, 1, 2, \dots$ . From [95], with  $q$  small and positive,  $A_{2n+1}^{(2n+1)}$  predominates in one series and  $B_{2n+1}^{(2n+1)}$  in the other. For example, if  $q = 1$ ,  $A_1^{(1)} \simeq 0.99$ , the remaining  $A$  being negligible:  $B_1^{(1)} \simeq 0.994$ , the remaining  $B$  being negligible. In these cases the sub-harmonic predominates. If  $q = 24$ ,  $A_1 \simeq 0.398$ ,  $A_3 \simeq -0.744$ ,  $A_5 \simeq 0.499$ ,  $A_7 \simeq -0.190$ , so the amplitudes of the  $3/2$  and  $5/2$  harmonics exceed that of the sub-harmonic: also  $B_1 \simeq 0.818$ ,  $B_3 \simeq -0.527$ ,  $B_5 \simeq 0.224$ , so the sub-harmonic predominates, but to a much smaller extent than for  $q = 1$ . Tabular values show that the amplitude of the sub-harmonic in  $se_1$  exceeds that in  $ce_1$ ,  $ce_3$ ,  $ce_5$ ,  $se_3$ ,  $se_5$  for  $q$  in  $0 < q \leq 40$ . (See § 29, p. 394.)

**15.42. Demonstration of sub-harmonic.** For this purpose the device of Fig. 28 is preferable to that of Fig. 5A. The link-mass-spring mechanism in the latter is replaced by a relatively heavy

FIG. 28. Dynamical device for illustrating sub-harmonic.

mass at the centre of a light flat strip of spring steel fixed at one end  $A$ , but free to move along the direction  $AB$  at the other end. So long as the pulsance of the driving force at  $B$  is small enough for absence of wave motion on the spring, this mechanism may be used to demonstrate the effect of varying the parameters  $m$ ,  $s$ ,  $\omega$ ,  $f_0$  in (1) § 15.40. In § 15.41 we showed that the best condition for a predominant sub-harmonic was with  $(a, q)$  on  $b_1$ ,  $q$  being small or moderate. Thus  $a = s/\omega^2 m$  and  $\gamma = f_0/2s$  must be small or moderate. To render the motion of  $m$  visible,  $\omega$  should be low, so  $m$  must be relatively large and  $f_0$  small, since we postulate  $s$  to be small. If it is not feasible to make  $\omega$  low enough, the motion of  $m$  could be rendered visible stroboscopically. By using suitable values of  $m$ ,  $s$ , the mechanisms of Figs. 5A, 28 may be used to demonstrate stability and instability.

**15.43. System of Fig. 5A with linear damping.** If  $r$  is a constant representing the resistance per unit velocity, (1) § 15.40 takes the form

$$m \frac{d^2 y}{dt^2} + r \frac{dy}{dt} + sy = (f_0 \cos 2\omega t)y. \quad (1)$$

Then with  $z = \omega t$  we get

$$y'' + 2\kappa y' + (\bar{a} - 2q \cos 2z)y = 0, \quad (2)$$

where  $\kappa = r/2\omega m$ ,  $\bar{a} = s/\omega^2 m$ ,  $2q = f_0/\omega^2 m$ . (2) is identical in form with (3) § 15.30, and the remarks in that section apply here also.

**15.50. Vibration of stretched string.** The classical case of a stretched string with immovable ends is a simple one. But when one end is held and the other is given a periodic motion along the length, the analysis is more complicated and leads to a Mathieu equation. We commence with constant tension and assume the string

FIG. 29. Illustrating a vibrating string with periodically varying tension superimposed upon constant tension.

to be elastic, uniform, and loss-free. Referring to Fig. 29, consider an elemental length  $ds$ .  $T$  is the horizontal component of the tension at  $ds$ , and  $T_1$  its vertical component. By similar triangles

$$\partial \xi / \partial x = T_1 / T, \quad \text{so } T_1 = T \partial \xi / \partial x. \quad (1)$$

The rate of change of  $T_1$  with respect to  $x$  is by (1)

$$\partial T_1 / \partial x = T \partial^2 \xi / \partial x^2, \quad (2)$$

so the difference in  $T_1$  at the ends of the element  $ds$  is

$$\partial T_1 = T dx \partial^2 \xi / \partial x^2. \quad (3)$$

When the amplitude of vibration is small, we may write  $dx$  for  $ds$ , so the vertical force to accelerate the element  $ds$  of mass  $m dx$  is

$$\partial T_1 = (m dx) \partial^2 \xi / \partial t^2. \quad (4)$$

Equating the r.h.s. of (3), (4) leads to the equation of motion, namely,

$$m dx \partial^2 \xi / \partial t^2 = T dx \partial^2 \xi / \partial x^2, \quad (5)$$

or

$$\frac{\partial^2 \xi}{\partial t^2} - \frac{T}{m} \frac{\partial^2 \xi}{\partial x^2} = 0. \quad (6)$$

**15.51. Solution of (6) § 15.50.** During vibration there are stationary waves on the string, the boundary conditions being  $\xi = 0$  at  $x = 0, l$ . Our solution must satisfy these. Now  $e^{ib(x+at)}$ , with  $\alpha^2 = T/m$ , satisfies the equation, so its real and imaginary parts must

both be solutions. Then  $e^{ib(x+\alpha t)} = \cos b(x+\alpha t) + i \sin b(x+\alpha t)$ , and since  $\xi = 0$  at  $x = 0$ , the solution cannot contain  $\cos bx$ . Thus of the four product pairs in the expansion of the real and imaginary parts we must choose  $\sin bx \sin b\alpha t$ ,  $\sin bx \cos b\alpha t$ . Hence the appropriate formal solution of (6) § 15.50 is

$$\xi = (A \sin b\alpha t + B \cos b\alpha t) \sin bx = f(t) \sin bx, \quad (1)$$

$A, B$  being arbitrary constants. Evanescence of  $\xi$  at  $x = 0, l$ , entails  $b = \pi n/l$ ,  $n$  a positive integer  $\neq 0$ . The pulsataces of the natural modes of vibration are given by  $\omega_n = b\alpha = (\pi n/l)(T/\mathbf{m})^{\frac{1}{2}}$ ,  $n = 1, 2, 3, \dots$ . The number of nodes *between* the ends of the string is  $(n-1)$ , and there are  $n$  antinodes or points of maximum displacement, corresponding to the  $n$ th mode of vibration.

**15.52. Periodically varying tension.** Suppose that, instead of being constant, the tension is expressed by  $T = T_0(1 - 2\gamma \cos 2\omega t)$ , then (6) § 15.50 becomes

$$\frac{\partial^2 \xi}{\partial t^2} - \frac{T_0}{\mathbf{m}}(1 - 2\gamma \cos 2\omega t) \frac{\partial^2 \xi}{\partial x^2} = 0 \quad (1)$$

with  $\gamma < \frac{1}{2}$ . By virtue of similarity we assume (1) § 15.51 as a solution and obtain the equation

$$\frac{d^2 f}{dt^2} + \frac{b^2 T_0}{\mathbf{m}}(1 - 2\gamma \cos 2\omega t)f = 0, \quad (2)$$

where  $f(t)$  is different from its former value. Writing  $z = \omega t$ ,  $a = b^2 T_0 / \omega^2 \mathbf{m}$ ,  $q = \gamma b^2 T_0 / \omega^2 \mathbf{m} = \gamma a$ , (2) transforms to the standard form

$$\frac{d^2 f}{dz^2} + (a - 2q \cos 2z)f = 0. \quad (3)$$

Since  $a = q/\gamma$  and  $\gamma < \frac{1}{2}$ , we get the case depicted in Fig. 25, where the straight line having this equation intersects all the characteristic curves. Unless the parameters  $a, q$  are specially selected, the point  $(a, q)$  will not in general lie on a characteristic for a function of integral order. Moreover, if  $(a, q)$  lies inside a stable region the motion will be represented by a Mathieu function of real fractional order, e.g.  $\text{ce}_{2n+\beta}(z, q)$ . In practice owing to damping, the motion once started would die away with increase in time.

**15.53. Melde's experiment.** This was described briefly in Chapter I. If an electrically maintained steel reed, having a frequency of the order 50 cycles per second, is used to vary the tension

of the string, the rate of vibration will be sensibly constant. The tension  $T_0$  or the length  $l$ , or both, may be adjusted so that the string vibrates without a node. Its pulsance is then half that of the reed, i.e. a subharmonic occurs. If now the string is stopped and released, its amplitude increases with increase in time, and attains an ultimate value. By reducing the *reed* amplitude such that  $q <$  some value  $q_0$ , the vibration of the string dies away. To explain these observations, terms representing both damping and non-linearity must be incorporated in the differential equation.

**15.54. The modified equation.** Adding viscous damping proportional to the velocity and a non-linear control term (odd in  $y$ , in virtue of symmetry of motion about the central position), we obtain

$$y'' + 2\kappa y' + (a + py^2 - 2q \cos 2z)y = 0 \quad (p > 0). \quad (1)$$

For a subharmonic to occur as in § 15.53,  $a \simeq 1$  and  $(a, q)$  lies in an *unstable* region between  $b_1$  and  $a_1$  in Fig. 11. A first approximation solution may be obtained by taking  $y = A_1 \cos z + B_1 \sin z$ . Then, with  $A = (A_1^2 + B_1^2)^{\frac{1}{2}}$ , the ultimate amplitude is

$$|A| \simeq [(4/3p)\{(1-a) + (q^2 - 4\kappa^2)^{\frac{1}{2}}\}]^{\frac{1}{2}}. \quad (2)$$

The condition for maintenance of the vibration, i.e. the reality of  $|A|$ , is

$$q > q_0 = \{4\kappa^2 + (1-a)^2\}^{\frac{1}{2}}. \quad (3)$$

Amplitude limitation is caused by a mis-tuning effect due to the non-linear tension control  $py^3$ .†

**15.55. String whose mass per unit length is periodic.** If in (6) § 15.50 we write  $\mathbf{m} = \mathbf{m}_0(1 - 2\gamma \cos \alpha_1 x)$  for  $\mathbf{m}$ , the equation becomes

$$g \frac{\partial^2 \xi}{\partial t^2} - \{T/[\mathbf{m}_0(1 - 2\gamma \cos \alpha_1 x)]\} \frac{\partial^2 \xi}{\partial x^2} = 0. \quad (1)$$

Assume that  $\xi = f(t)g(x)$ , where  $f$  is a function of  $t$  alone, and  $g$  one of  $x$  alone. Then

$$g \frac{d^2 f}{dt^2} - \{T/[\mathbf{m}_0(1 - 2\gamma \cos \alpha_1 x)]\} f \frac{d^2 g}{dx^2} = 0. \quad (2)$$

Dividing (2) throughout by  $fg$  leads to

$$\frac{1}{f} \frac{d^2 f}{dt^2} = \{T/[\mathbf{m}_0(1 - 2\gamma \cos \alpha_1 x)]\} \frac{1}{g} \frac{d^2 g}{dx^2}. \quad (3)$$

† A detailed analysis is given in McLachlan, *Ordinary Non-linear Differential Equations in Engineering and Physical Sciences* (Oxford, 1950).

Since the l.h.s. is independent of  $x$  and the r.h.s. of  $t$ , each must be a constant, say,  $\lambda^2$ . Then using the l.h.s. and the separation constant  $\lambda^2$ , we get

$$\frac{d^2 f}{dt^2} + \lambda^2 f = 0, \quad (4)$$

$$\text{so} \quad f = \sin \lambda t \quad \text{or} \quad \cos \lambda t. \quad (5)$$

From the r.h.s. of (3) we get

$$\frac{d^2 g}{dx^2} + \frac{\lambda^2}{T} \mathbf{m}_0 (1 - 2\gamma \cos \alpha_1 x) g = 0, \quad (6)$$

$$\text{or} \quad \frac{d^2 g}{dz^2} + a(1 - 2\gamma \cos 2z) g = 0, \quad (7)$$

where  $z = \frac{1}{2}\alpha_1 x$ ,  $a = 4\lambda^2 \mathbf{m}_0 / \alpha_1^2 T$ ,  $q = a\gamma$ ,  $\gamma < 0.5$ .

The solution of (7) should be stable and satisfy the boundary condition  $g = 0$  at  $x = 0, l$ . The stable solutions for  $q > 0$  are given at (1)–(4) § 4.71. The boundary condition excludes (1), (3) § 4.71, so we consider (2), (4) § 4.71. Now  $g$  in (6) may or may not be periodic in  $x$ . If periodic,  $\beta = p/s$ , a rational fraction in its lowest terms,  $0 < \beta < 1$ . Write  $z = s\pi x/l$ , then

$$\sin(2r + p/s)(s\pi x/l) = \sin(2r + 1 + p/s)(s\pi x/l) = 0$$

for all  $r$  when  $x = 0, l$ . Hence we may take  $\text{se}_{m+p/s}(s\pi x/l, q)$  as those solutions of (6) which satisfy the boundary condition.

Before the complete solution can be written down we have to determine  $\lambda$ . As in §§ 15.22, 15.41 we have the relationship  $a = q/\gamma$ ,  $\gamma$  being a known constant. Then the straight line so defined may be drawn as shown in Fig. 27. Its intersections with the iso- $p/s$  curves for  $\text{se}_{m+p/s}(z, q)$ —see the iso- $\beta$  curves of Fig. 11—give the values of  $(a, q)$  for which (6) satisfies the boundary condition. Then we have  $\lambda_{m+p/s}^2 = a_{m+p/s} \alpha_1^2 T / 4\mathbf{m}_0$ . If there is an integral number of periods of mass-distribution on the string, we may take  $\alpha_1 = 2n\pi/l$ , so the pulsance of the vibration is

$$\lambda_{m+p/s} = \frac{n\pi}{l} (a_{m+p/s} T / \mathbf{m}_0)^{\frac{1}{2}}. \quad (8)$$

Then the complete solution of (1), with two arbitrary constants, appropriate to the boundary condition, is

$$\xi = \sum_{m=0}^{\infty} [A_m \cos \lambda_{m+p/s} t + B_m \sin \lambda_{m+p/s} t] \text{se}_{m+p/s} \left( \frac{s\pi x}{l}, a_{m+p/s} \gamma \right). \quad (9)$$

**15.60. Column subjected to axial pull with periodic component [121].** Referring to Fig. 30, the pin-jointed column sustains a steady axial pull  $P_0$ , but owing to out-of-balance machinery an alternating or ripple component  $-2\gamma P_0 \cos 2\omega t$  is superimposed thereon. Thus the total instantaneous axial load is  $P = P_0(1 - 2\gamma \cos 2\omega t)$ ,

FIG. 30. Illustrating a long column with pinned ends: a periodic force is superimposed upon a constant axial pull.

where usually  $\gamma < 0.5$ . To render the analysis tractable we make the following assumptions:

1. The column is a uniform solid or hollow homogeneous cylinder, its outer diameter being small compared with the length  $l$ .
2. The lateral displacement due to  $P$  is small compared with  $l$ .
3. The maximum stress is within the elastic limit of the material.
4. Shear stress and rotatory inertia are negligible.
5. The ripple pulsance is well below that of the first longitudinal mode of the column, i.e. there is no longitudinal wave motion, and the column moves substantially as a whole in an *axial* direction.

Let  $E$  = Young's modulus of elasticity;

$I$  = second moment of cross-section about a diameter;

$m$  = mass of unit length of the column;

$\xi$  = lateral displacement at any point distant  $x$  from the right end (Fig. 30).

Then it may be shown that the equation of motion is

$$EI \frac{\partial^4 \xi}{\partial x^4} - P_0(1 - 2\gamma \cos 2\omega t) \frac{\partial^2 \xi}{\partial x^2} + m \frac{\partial^2 \xi}{\partial t^2} = 0, \quad (1)$$

$$\text{or} \quad \frac{\partial^2 \xi}{\partial t^2} - \frac{P_0}{m}(1 - 2\gamma \cos 2\omega t) \frac{\partial^2 \xi}{\partial x^2} + \frac{EI}{m} \frac{\partial^4 \xi}{\partial x^4} = 0. \quad (2)$$

The displacement  $\xi$  and the bending moment  $EI \partial^2 \xi / \partial x^2$  must vanish

at the ends of a pinned column. Thus the boundary conditions are  $\xi = 0$ ,  $\partial^2 \xi / \partial x^2 = 0$  at  $x = 0, l$ . From §§ 15.51, 15.52 we see that a solution of the form  $\xi = f(t) \sin bx$ , with  $b = n\pi/l$ , satisfies these conditions. Substituting this solution in (2) leads to the equation

$$\frac{d^2 f}{dt^2} + \left[ \frac{b^2}{m} (EIb^2 + P_0) - 2\gamma \frac{P_0 b^2}{m} \cos 2\omega t \right] f = 0. \quad (3)$$

Writing  $z = \omega t$ ,  $a = b^2(EIb^2 + P_0)/\omega^2 m$ ,  $q = \gamma P_0 b^2/\omega^2 m$ , (3) takes the standard form

$$\frac{d^2 f}{dz^2} + (a - 2q \cos 2z)f = 0. \quad (4)$$

If now we write  $\gamma_1 = \gamma P_0/(P_0 + EIb^2)$ , (4) becomes

$$\frac{d^2 f}{dz^2} + a(1 - 2\gamma_1 \cos 2z)f = 0, \quad (5)$$

so the question of stability for a given  $n$  in  $b = n\pi/l$  may be considered in the same way as in § 15.23. The stability in practice exceeds that predicted from theory owing to internal loss in the material, and an idealized equation incorporating this loss takes the form at (2) § 15.43.

The complete solution of (2), with constants  $A_n$ , may be written

$$\xi = \sum_{n=1}^{\infty} A_n f_n(t) \sin \frac{n\pi x}{l}, \quad (6)$$

$f_n(t)$  being that solution of (4) corresponding to the particular  $n$ . Proof of the convergence of a solution of type (6) will be found in reference [121].

When the inherent stiffness of the column vanishes, it may be regarded as a flexible string. To obtain this metamorphosis mathematically, we write  $EI = 0$  in (3), thereby reducing it to

$$\frac{d^2 f}{dt^2} + \frac{b^2 P_0}{m} (1 - 2\gamma \cos 2\omega t)f = 0, \quad (7)$$

which is identical with (2) § 15.52, but with  $P_0$  for  $T_0$ . The stability of both column and string is discussed at some length in [121], to which reference may be made.

## XVI

### APPLICATION OF THE WAVE EQUATION TO VIBRATIONAL SYSTEMS

**16.10. Elliptical membrane [130].** Let  $\mathbf{m}$  be the mass per unit area,  $\mathbf{T}$  the uniform tension per unit arc length,†  $\zeta$  the displacement normal to the equilibrium plane of the membrane (horizontal). Then *in vacuo* the equation of motion of a homogeneous loss-free membrane in the  $x, y$  plane is

$$\frac{\partial^2 \zeta}{\partial x^2} + \frac{\partial^2 \zeta}{\partial y^2} - \frac{\mathbf{m}}{\mathbf{T}} \frac{\partial^2 \zeta}{\partial t^2} = 0. \quad (1)$$

This is (6) § 15.50 with the addition of the term  $-(\mathbf{T}/\mathbf{m})(\partial^2 \zeta / \partial y^2)$ , thereby including the coordinate  $y$ . If  $\zeta$  varies sinusoidally with time  $t$ , we may take  $\zeta = e^{i\omega t} f(x, y)$ , so that (1) becomes

$$\frac{\partial^2 \zeta}{\partial x^2} + \frac{\partial^2 \zeta}{\partial y^2} + \frac{\mathbf{m}}{\mathbf{T}} \omega^2 \zeta = 0. \quad (2)$$

Comparison with (1) § 9.10 shows that  $k_1^2 = \mathbf{m}\omega^2/\mathbf{T}$ , so

$$2q = \mathbf{m}\omega^2 h^2 / 2\mathbf{T}.$$

Hence with this value of  $2q$ , (3), (4) § 9.21 are the ordinary differential equations into which (2), expressed in elliptic coordinates, may be divided. The appropriate solutions, in product form, may be selected from Tables 10–12 to satisfy the physical conditions of the problem.

**16.11. Physical conditions.** Referring to Fig. 31, if we start at  $\eta = 0$  and move counter-clockwise round a confocal ellipse  $\xi = \xi_1 < \xi_0$  the displacement  $\zeta$  at any instant alters continuously. It *may* be repeated between  $\eta = \pi$  and  $\eta = 2\pi$ , but it *is* repeated after  $\eta = 2\pi$ . Hence  $\zeta$  is single-valued and periodic in the coordinate  $\eta$ . The period is either  $\pi$  or  $2\pi$ , so that  $\zeta(\xi, \eta) = \zeta(\xi, \eta + \pi)$  or  $\zeta(\xi, \eta + 2\pi)$  as the case may be. Thus of the product functions in  $\zeta = \psi(\xi)\phi(\eta)$ , we must have  $\phi(\eta) = \text{ce}_m(\eta)$  or  $\text{se}_m(\eta)$  or a constant multiple thereof.

In addition to periodicity in  $\eta$ , at any point  $(0, \eta)$  and the corresponding point  $(0, -\eta)$  on the interfocal line, we must have:

(a) continuity of displacement, i.e.

$$\zeta(0, \eta) = \zeta(0, -\eta); \quad (3)$$

† To obtain uniform radial tension per unit arc length, the membrane is stretched uniformly and clamped between circular rings. Elliptical rings are then clamped on the membrane within the circular ones.

(b) continuity of gradient, i.e.

$$\frac{\partial}{\partial \xi} [\zeta(\xi, \eta)]_{\xi \rightarrow 0} = -\frac{\partial}{\partial \xi} [\zeta(\xi, -\eta)]_{\xi \rightarrow 0}. \quad (4)$$

These two conditions imply continuity of displacement and gradient in crossing the interfocal line orthogonally.

FIG. 31. Diagram for membranal problem, from which the Mathieu functions originated.

For  $\zeta = \text{Ce}_m(\xi)\text{ce}_m(\eta)$ ,  $\text{Ce}_m(0)$  is a non-zero constant, while  $\text{ce}_m(\eta) = \text{ce}_m(-\eta)$ . Hence (a) is satisfied. Also

$$\text{ce}_m(\pm\eta) \frac{\partial}{\partial \xi} \text{Ce}_m(\xi)_{\xi \rightarrow 0} = 0, \quad (5)$$

so (b) is satisfied.

For  $\zeta = \text{Se}_m(\xi)\text{se}_m(\eta)$ ,  $\zeta(0) = 0$ , so (a) is satisfied, while

$$\text{se}_m(\eta) \frac{\partial}{\partial \xi} \text{Se}_m(\xi)_{\xi \rightarrow 0} = -\text{se}_m(-\eta) \frac{\partial}{\partial \xi} \text{Se}_m(\xi)_{\xi \rightarrow 0} \quad (6)$$

thereby satisfying (b).

For  $\zeta = \text{Fe}_m(\xi)\text{ce}_m(\eta)$ ,  $\text{Fe}_m(0) = 0$ , so (a) is satisfied, but

$$\text{ce}_m(\eta) \frac{\partial}{\partial \xi} \text{Fe}_m(\xi)_{\xi \rightarrow 0} = \text{ce}_m(-\eta) \frac{\partial}{\partial \xi} \text{Fe}_m(\xi)_{\xi \rightarrow 0} \neq 0, \quad (7)$$

except for special values of  $\eta$ , so in general (b) is not satisfied. Proceeding in this way, we find that the only permissible forms of solution are

$$\zeta(\xi, \eta, t) = C_m \text{Ce}_m(\xi, q) \text{ce}_m(\eta, q) \cos(\omega_m t + \epsilon_m) \quad (a_m) \quad (8)$$

$$\text{and} \quad \zeta(\xi, \eta, t) = S_m \text{Se}_m(\xi, q) \text{se}_m(\eta, q) \cos(\bar{\omega}_m t + \bar{\epsilon}_m) \quad (b_m). \quad (9)$$

$C_m$ ,  $S_m$  are arbitrary constants determinable from the conditions specified for the configuration of and velocity distribution over the membrane at  $t = 0$ .  $\omega_m$  is the pulsance of the  $m$ th free mode of vibration, and  $\epsilon_m$  its relative phase angle. Since each integral value gives a separate solution of the differential equation, the complete solution of (1) § 16.10 when expressed in elliptic coordinates is

$$\zeta(\xi, \eta, t) = \sum_{m=0}^{\infty} C_m \text{Ce}_m(\xi, q) \text{ce}_m(\eta, q) \cos(\omega_m t + \epsilon_m) + \\ + \sum_{m=1}^{\infty} S_m \text{Se}_m(\xi, q) \text{se}_m(\eta, q) \cos(\bar{\omega}_m t + \bar{\epsilon}_m). \quad (10)$$

**16.12. Symmetry.** In any product pair solutions, Ce or Se is constant on any confocal ellipse. Hence the symmetry is governed by ce or se. Since  $\text{ce}_{2n}(\eta, q) = \text{ce}_{2n}(\pi \pm \eta, q) = \text{ce}_{2n}(2\pi - \eta, q)$ , it follows that the displacement expressed by  $\text{Ce}_{2n}(\xi, q) \text{ce}_{2n}(\eta, q)$  is symmetrical about both the major and minor axes of the ellipse.  $\text{ce}_{2n+1}(\eta, q) = -\text{ce}_{2n+1}(\pi \pm \eta, q) = \text{ce}_{2n+1}(2\pi - \eta, q)$ , so that the displacement expressed by  $\text{Ce}_{2n+1}(\xi, q) \text{ce}_{2n+1}(\eta, q)$  is symmetrical about the major axis but anti-symmetrical about the minor axis.

$$\text{se}_{2n+1}(\eta, q) = \mp \text{se}_{2n+1}(\pi \pm \eta, q) = -\text{se}_{2n+1}(2\pi - \eta, q),$$

so  $\text{Se}_{2n+1}(\xi, q) \text{se}_{2n+1}(\eta, q)$  corresponds to a displacement anti-symmetrical about the major axis but symmetrical about the minor axis. Finally  $\text{se}_{2n+2}(\eta, q) = \pm \text{se}_{2n+2}(\pi \pm \eta, q) = -\text{se}_{2n+2}(2\pi - \eta, q)$ , so  $\text{Se}_{2n+2}(\xi, q) \text{se}_{2n+2}(\eta, q)$  corresponds to a displacement anti-symmetrical about both axes. These deductions will be understood more readily by reference to Figs. 1–4. As a guide to memorization, it may be remarked that the symmetry or anti-symmetry about the major and minor axes is the same as that for the degenerate forms  $\cos mz$ ,  $\sin mz$  about  $z = 0$ ,  $\frac{1}{2}\pi$ , respectively (see remark at end of § 12.10).

**16.13. Vibrational modes of membrane.** Each individual solution in (10) § 16.11 for  $m = 0, 1, 2, \dots$  corresponds to a different mode of vibration. When  $q$  has its appropriate value, the dynamic deformation surface of the membrane and the pulsance differ for each  $m$ . Any mode may exist separately—at least in theory—or they may all be present. The maximum displacement of the surface for a particular mode depends upon the value of  $C_m$  or  $S_m$ . These in turn are governed by the configuration of and the normal velocity

distribution over the membrane at time  $t = 0$ . For instance, it might be pulled from the centre into a conoidal shape and released at  $t = 0$ .

The boundary condition for all  $\eta$  is that  $\zeta = 0$  at the clamping rings where  $\xi = \xi_0$ . Since  $ce_m(\eta, q)$ ,  $se_m(\eta, q)$  are independent of  $\xi$ , we must have

$$Ce_m(\xi_0, q) = 0 \quad \text{for } m = 0, 1, 2, \dots \quad (1)$$

$$\text{and} \quad Se_m(\xi_0, q) = 0 \quad \text{for } m = 1, 2, \dots \quad (2)$$

Now  $\xi_0$  is fixed, so we need those positive values of  $q$ , say  $q_{m,r}$ ,  $\bar{q}_{m,r}$  for which the respective functions in (1), (2) vanish. These may be regarded as the positive parametric zeros of the functions. They define a series of confocal nodal ellipses. There is an infinity of zeros for each  $m$ , i.e. one for each  $r = 1, 2, 3, \dots$ . Hence for  $Ce_m$ , if  $r = p$ , there are  $(p-1)$  nodal ellipses *within* the clamping rings, and likewise for  $Se_m$ , but their locations differ. (1), (2) are known as the period or pulsance equations, since their roots are used to calculate the pulsances of the modes of the membrane.

For  $q > 0$ ,  $m \geq 1$ , the functions  $ce_m(\eta, q)$ ,  $se_m(\eta, q)$  have zeros in  $\eta$  (see Chap. XII). Hence  $\zeta$  in (8), (9) § 16.11 vanishes also if  $\eta$  satisfies the respective equations

$$ce_m(\eta, q_{m,r}) = 0 \quad (3)$$

$$\text{and} \quad se_m(\eta, \bar{q}_{m,r}) = 0. \quad (4)$$

The roots define a series of confocal nodal hyperbolas. Now  $ce_m(\eta, q_{m,r})$ ,  $se_m(\eta, \bar{q}_{m,r})$  each have  $m$  zeros in  $0 \leq \eta < \pi$  (see § 12.10), so for a given  $m$  each function gives rise to  $m$  nodal hyperbolas.

**16.14. Expansion of function.** From physical considerations it is clear that  $\zeta$  in (10) § 16.11 must be a continuous function of  $\xi$ ,  $\eta$ , within the ellipse, which vanishes at its periphery. This suggests the *Theorem*: That any function of  $\xi$ ,  $\eta$ , continuous and single-valued within the ellipse, which vanishes on its boundary, may be expanded at any point of the interior in the form of a double series, namely [52]

$$\begin{aligned} \zeta(\xi, \eta) = & \sum_{m=0}^{\infty} \left[ \sum_{r=1}^{\infty} C_{m,r} Ce_m(\xi, q_{m,r}) ce_m(\eta, q_{m,r}) \right] + \\ & + \sum_{m=1}^{\infty} \left[ \sum_{r=1}^{\infty} S_{m,r} Se_m(\xi, \bar{q}_{m,r}) se_m(\eta, \bar{q}_{m,r}) \right]. \quad (1) \end{aligned}$$

A formal proof of the theorem is outside our present purview.

**16.15. Determination of  $C_{m,r}$ ,  $S_{m,r}$ .** Suppose that  $\zeta(\xi, \eta)$  has the properties stated above. Multiply both sides of (1) § 16.14 by

$$(\cosh 2\xi - \cos 2\eta) \text{Ce}_n(\xi, q_{n,p}) \text{ce}_n(\eta, q_{n,p}), \quad (1)$$

and integrate with respect to  $\eta$  from 0 to  $2\pi$ , and with respect to  $\xi$  from 0 to  $\xi_0$ . Then by (7) § 9.40 all terms vanish except when  $n = m$ ,  $r = p$ . Hence

$$\begin{aligned} \int_0^{\xi_0} \int_0^{2\pi} \text{Ce}_m(\xi, q_{m,r}) \text{ce}_m(\eta, q_{m,r}) (\cosh 2\xi - \cos 2\eta) \zeta(\xi, \eta) d\xi d\eta \\ = C_{m,r} \int_0^{\xi_0} \int_0^{2\pi} \text{Ce}_m^2(\xi, q_{m,r}) \text{ce}_m^2(\eta, q_{m,r}) (\cosh 2\xi - \cos 2\eta) d\xi d\eta. \end{aligned} \quad (2)$$

Now by (7) § 14.40

$$\int_0^{2\pi} \text{ce}_m^2(\eta, q_{m,r}) \cos 2\eta d\eta = \pi \Theta_{m,r} \quad (3)$$

so we obtain

$$C_{m,r} = \frac{\int_0^{\xi_0} \int_0^{2\pi} \text{Ce}_m(\xi, q_{m,r}) \text{ce}_m(\eta, q_{m,r}) \zeta(\xi, \eta) (\cosh 2\xi - \cos 2\eta) d\xi d\eta}{\pi \int_0^{\xi_0} \text{Ce}_m^2(\xi, q_{m,r}) [\cosh 2\xi - \Theta_{m,r}] d\xi}. \quad (4)$$

In like manner we can show that

$$S_{m,r} = \frac{\int_0^{\xi_0} \int_0^{2\pi} \text{Se}_m(\xi, \bar{q}_{m,r}) \text{se}_m(\eta, \bar{q}_{m,r}) \zeta(\xi, \eta) (\cosh 2\xi - \cos 2\eta) d\xi d\eta}{\pi \int_0^{\xi_0} \text{Se}_m^2(\xi, \bar{q}_{m,r}) [\cosh 2\xi - \Psi_{m,r}] d\xi}. \quad (5)$$

The denominators of (4), (5) may be evaluated numerically (see § 9.40).

**16.16. Transition to circular membrane.** Using the results in Appendix I, and omitting the time factor, (10) § 16.11 degenerates to the well-known form [202, p. 27]

$$\zeta(r, \theta) = \sum_{m=0}^{\infty} C'_m J_m(k_1 r) \cos m\theta + \sum_{m=1}^{\infty} S'_m J_m(k_1 r) \sin m\theta, \quad (1)$$

where  $C'_m = p'_m C_m$ ,  $S'_m = s'_m S_m$ . The pulsance equations (1), (2) § 16.13 become

$$J_m(k_1 a) = 0, \quad (2)$$

whose roots define the nodal circles, while the nodal diameters are defined by the roots of

$$\cos\{m\theta - \tan^{-1}(S'_m/C'_m)\} = 0. \quad (3)$$

**16.17. Example.** We shall consider the mode in which the displacement is proportional to  $Ce_1(\xi, q_{1,1})ce_1(\eta, q_{1,1})$ , with  $a = 5$  cm.,  $b = 3$  cm.,  $e = 0.8$ . The first step is to calculate  $q_{1,1}$ , the lowest positive parametric zero, for which

$$Ce_1(\xi_0, q_{1,1}) = 0. \quad (1)$$

Then  $e^{-1} = \cosh \xi_0 = 1.25$ , and from tables  $\xi_0 = 0.6931$ : also  $e^{\xi_0} = 2$ ,  $e^{-\xi_0} = \frac{1}{2}$ ,  $e$  in these latter cases being Napier's base. Writing  $i\xi_0$  for  $z$  in (16) § 2.13, we obtain to order 3 in  $q$ —this being adequate for illustration—

$$Ce_1(\xi_0, q) \simeq -\alpha^3(\tfrac{1}{18} \cosh 7\xi_0 - \tfrac{1}{3} \cosh 5\xi_0 + \tfrac{1}{3} \cosh 3\xi_0) + \\ + \alpha^2(\tfrac{1}{3} \cosh 5\xi_0 - \cosh 3\xi_0) - \alpha \cosh 3\xi_0 + \cosh \xi_0 = 0, \quad (2)$$

where  $\alpha = \frac{1}{2}q$ . Using the preceding numerical values in (2) leads to the approximate equation

$$\alpha^3 + 0.578\alpha^2 - 1.85\alpha + 0.569 = 0, \quad (3)$$

whose lowest root is found to be  $\alpha \simeq 0.393$ . By § 16.10 the pulsance of the mode in question is

$$\omega_1 = k_1(T/m)^{\frac{1}{2}}. \quad (4)$$

Now  $k_1 h = 2q^{\frac{1}{2}}$ ,  $h = ae = 4$ , so with  $q_{1,1} = 8\alpha = 3.144$ ,  $k_1 = 0.886$ , and (4) gives

$$\omega_1 = 0.886(T/m)^{\frac{1}{2}}. \quad (5)$$

Omitting the time factor, the normal displacement of the membrane at any point  $(\xi, \eta)$ , is expressed by

$$\zeta_1(\xi, \eta) = C_1 Ce(\xi, q_{1,1})ce(\eta, q_{1,1}), \quad (6)$$

$C_1$  being an arbitrary constant dependent upon the greatest amplitude. The corresponding cartesian coordinates are  $x = h \cosh \xi \cos \eta$ ,  $y = h \sinh \xi \sin \eta$ , with  $h = ae = 4$ . Since  $ce_1(\eta, q_{1,1}) = 0$  when  $\eta = \frac{1}{2}\pi, \frac{3}{2}\pi$ , the minor axis is a nodal line. Some idea of the configuration of the membrane at any instant may be gleaned from the graph of  $ce_1(\eta, q)$  in Fig. 1. The displacement is symmetrical about the major, but anti-symmetrical about the minor axis.

**16.18. Transition to circular membrane.** If we apply the formulae in Appendix I when  $e \rightarrow 0$ ,  $a$  remaining constant, (6) § 16.17 degenerates to

$$\zeta_1(r, \theta) = C'_1 J_1(k_1 r) \cos \theta. \quad (1)$$

When  $\theta = \frac{1}{2}\pi, \frac{3}{2}\pi$ ,  $\cos \theta = 0$ , so there is a nodal diameter. The

first positive zero of  $J_1(k_1 a)$  is  $k_1 a = 3.832$ , and since  $a = 5$  cm.,  $k_1 = 3.832/5 = 0.766$ . Then

$$\omega_1 = k_1(T/m)^{\frac{1}{2}} = 0.766(T/m)^{\frac{1}{2}}. \quad (2)$$

Comparing this with (5) § 16.17, we find that with  $a$  constant, an increase in  $e$  from 0 to 0.8 raises the pulsance of the mode by about 16 per cent.

**16.20. Free oscillations of water in elliptical lake [104].** In Fig. 32 A,  $\zeta$  is the vertical displacement of the water surface from its

FIG. 32. (A), (B) Illustrating problem of elliptical lake.

equilibrium position, and  $d$  the uniform depth. We assume that (1) the lake is stationary in space, (2)  $\zeta$  varies as  $e^{i\omega t}$  with respect to time. If the displacement is small enough for its square to be neglected, it can be shown that the differential equation of motion in rectangular coordinates is

$$\frac{\partial^2 \zeta}{\partial x^2} + \frac{\partial^2 \zeta}{\partial y^2} + \frac{\omega^2}{c^2} \zeta = 0, \quad (1)$$

where  $c^2 = gd$ ,  $c$  being the velocity of a free wave in a very large expanse of water of uniform depth  $d$ , and  $g$  the acceleration due to gravity. Applying the transformation in § 9.20 to (1) leads to

$$\frac{\partial^2 \zeta}{\partial \xi^2} + \frac{\partial^2 \zeta}{\partial \eta^2} + 2k^2 (\cosh 2\xi - \cos 2\eta) \zeta = 0, \quad (2)$$

with  $2k = \omega h/c$ . Then, by an argument akin to that in §16.11, it can be shown that the required solution takes the form

$$\begin{aligned} \zeta(\xi, \eta, t) = \sum_{m=0}^{\infty} C_m \text{Ce}_m(\xi, q) \text{ce}_m(\eta, q) \cos(\omega_m t + \epsilon_m) + \\ + \sum_{m=1}^{\infty} S_m \text{Se}_m(\xi, q) \text{se}_m(\eta, q) \cos(\bar{\omega}_m t + \bar{\epsilon}_m). \end{aligned} \quad (3)$$

When the appropriate value of  $q$  is assigned, each term of the series in (3) corresponds to a normal mode of oscillation. There are two types of mode, namely,  $\text{Ce}_m \text{ce}_m$  and  $\text{Se}_m \text{se}_m$ . An infinity of modes of either type corresponds to each  $m$ . The instantaneous displacements of the water for these modes are proportional, respectively, to

$$\text{Ce}_m(\xi, q) \text{ce}_m(\eta, q) \cos(\omega_m t + \epsilon_m)$$

and

$$\text{Se}_m(\xi, q) \text{se}_m(\eta, q) \cos(\bar{\omega}_m t + \bar{\epsilon}_m), \quad (4)$$

$q$  having an infinity of values for each  $m$ . Each corresponds to a distinctive dynamic deformation surface of the water. When the appropriate values  $C_m, S_m$  are used,  $\zeta$  in (3) represents the configuration of the surface of the water at any instant  $t \geq 0$ . As usual  $C_m, S_m$  are obtained by aid of the displacement and velocity distribution over the surface at  $t = 0$ .

**16.21. Boundary condition.** Consider any elemental arc length  $ds$ , and another one  $dn$  normal thereto, as depicted in Fig. 32B. Then it may be deduced that the water-particle velocity in the direction of  $dn$  is

$$u_n = \frac{ig}{\omega} \frac{\partial \zeta}{\partial n}. \quad (1)$$

By (6) §9.12,  $dn = ds_1 = l_1 d\xi$ , so (1) may be written

$$u_n = \frac{ig}{\omega l_1} \frac{\partial \zeta}{\partial \xi}. \quad (2)$$

At the boundary of the lake,  $\xi = \xi_0$ , and the velocity of the water normal thereto is zero. Hence at  $\xi = \xi_0$ ,  $u_n = 0$ , so the boundary condition is

$$\left[ \frac{\partial \zeta}{\partial \xi} \right]_{\xi=\xi_0} = 0. \quad (3)$$

In the pairs of product functions  $Ce_m ce_m$ ,  $Se_m se_m$  in (3) § 16.20,  $ce_m$ ,  $se_m$  are independent of  $\xi$ . Thus (3) entails

$$Ce'_m(\xi_0, q) = 0 \quad (4)$$

and

$$Se'_m(\xi_0, q) = 0, \quad (5)$$

so we require  $q_{m,p}$ ,  $\bar{q}_{m,p}$ , the positive parametric zeros of  $Ce'_m$  and  $Se'_m$  respectively. (4), (5) are designated the pulsatace or period equations.

**16.22. Expansion of function.** From purely physical considerations it is evident that, omitting the time factor,  $\zeta$  in (3) § 16.20 must be a function continuous within the ellipse, but having zero normal gradient at its boundary. This suggests the *Theorem*: That any function of  $(\xi, \eta)$  continuous and single-valued within the ellipse, having zero normal gradient at its boundary, may be expanded at any point of the interior in the form of a double series like (1) § 16.14 [52]. In the present case the values of  $q$  are designated  $q_{m,p}$ ,  $\bar{q}_{m,p}$ , these being the positive parametric roots of

$$Ce'_m(\xi_0, q) = 0 \quad (1)$$

and

$$Se'_m(\xi_0, q) = 0. \quad (2)$$

The coefficients  $C_m$ ,  $S_m$  in the expansion are determined in a way similar to that in § 16.15.

**16.23. Example.** To illustrate the analysis in § 16.20 et seq., we shall consider the mode defined by  $m = 1$ ,  $p = 1$ , the tide height being proportional to  $Ce_1(\xi, q_{1,1})ce_1(\eta, q_{1,1})$ . If the eccentricity of the ellipse is  $e = 0.8$ , then the ratio of the axes is  $b/a = (1 - e^2)^{\frac{1}{2}} = 0.6$ . To determine the pulsatace of the water mainly parallel to the direction of the major axis, we have to calculate  $q_{1,1}$ , such that

$$Ce'_1(\xi_0, q_{1,1}) = 0. \quad (1)$$

Differentiating (2) § 16.17 with respect to  $\xi$  and putting  $\alpha = \frac{1}{3}q$ , we get

$$Ce'_1(\xi_0, q) \simeq -\alpha^3 \left( \frac{7}{18} \sinh 7\xi_0 - \frac{20}{9} \sinh 5\xi_0 + \sinh 3\xi_0 \right) + \alpha^2 \left( \frac{1}{3} \sinh 5\xi_0 - 3 \sinh 3\xi_0 \right) - 3\alpha \sinh 3\xi_0 + \sinh \xi_0 = 0. \quad (2)$$

Now  $\cosh \xi_0 = e^{-1} = 1.25$ ,  $\xi_0 = 0.6931$ ,  $e^{\xi_0} = 2$ , and  $e^{-\xi_0} = 0.5$ . Expressing the hyperbolic functions in exponentials and using these numerical values leads to the approximate equation

$$13.4\alpha^3 + 29.7\alpha^2 - 23.6\alpha + 1.5 = 0. \quad (3)$$

The smallest positive root of (3) is  $\alpha \simeq 0.07$ , so  $q_{1,1} \simeq 0.56$ . Since  $4q = \omega^2 h^2 / c^2$ , with  $h = ae$ , we have

$$\omega_1^2 = 4q_{1,1} c^2 / a^2 e^2. \quad (4)$$

With the above numerical values (4) yields [104]

$$\omega_1 \simeq 1.87c/a. \quad (5)$$

For the corresponding mode of a circular lake of radius  $a$  the

FIG. 33. Diagrams for lowest asymmetrical mode of water in elliptical lake.

(A) Velocity  $u$  in  $x$  direction.

(B) Tide height  $\zeta$ .

boundary condition is given by the degenerate form of (4), (5) § 16.21 (see Appendix I), so

$$J'_1(\omega_1 a/c) = 0, \quad (6)$$

and from Bessel-function tables we find that the lowest root is

$$\omega_1 a/c \simeq 1.84 \quad \text{or} \quad \omega_1 \simeq 1.84c/a. \quad (7)$$

Thus the pulsance of the mode for a lake having eccentricity  $e = 0.8$  is only 1.6 per cent. higher than that for  $e = 0$ . Moreover, in a practical sense the decrease in width of the lake from  $2a$  to  $1.2a = 2b$  has a negligible influence on the pulsance of the (mainly) longitudinal oscillation. For this mode, since

$$\zeta_1 \propto Ce_1(\xi, q_{1,1})ce_1(\eta, q_{1,1}), \quad (8)$$

the vertical displacement of the water surface is symmetrical about the major axis, but anti-symmetrical with respect to the minor axis, as illustrated in Fig. 33 B, and demonstrated analytically in § 16.12.

The minor axis is defined by  $x = 0$ , so  $x = h \cosh \xi \cos \eta = 0$ , giving  $\eta = \frac{1}{2}\pi$  or  $\frac{3}{2}\pi$ . Thus  $ce_1(\eta, q_{1,1}) = 0$ , so  $\zeta = 0$ , and the minor axis is a nodal line.

**16.24. Example.** We now pass on to study the mode  $m = 1$ ,  $p = 1$  in which the tide height is proportional to  $Se_1(\xi, \bar{q}_{1,1})se_1(\eta, \bar{q}_{1,1})$ , the oscillation being mainly *across* the lake.† Since  $se_1 = 0$  when  $\eta = 0, \pi$ , the major axis is a nodal line. The pulsance equation is

$$Se'_1(\xi_0, \bar{q}_{1,1}) = 0, \quad (1)$$

and we have to calculate the smallest  $\bar{q} > 0$  to satisfy this. Writing  $iz$  for  $z$  in (2) § 2.14, and differentiating with respect to  $z$ , gives, with  $\bar{\alpha} = \frac{1}{3}\bar{q}$ ,

$$Se'_1(\xi_0, \bar{q}) \simeq -\bar{\alpha}^3(\frac{7}{18} \cosh 7\xi_0 + \frac{20}{9} \cosh 5\xi_0 + \cosh 3\xi_0) + \bar{\alpha}^2(\frac{5}{3} \cosh 5\xi_0 + 3 \cosh 3\xi_0) - 3\bar{\alpha} \cosh 3\xi_0 + \cosh \xi_0 = 0. \quad (2)$$

Proceeding as in § 16.23 we arrive at the approximate equation

$$129 \cdot 1 \bar{\alpha}^3 - 77 \cdot 7 \bar{\alpha}^2 + 24 \cdot 4 \bar{\alpha} - 2 \cdot 5 = 0, \quad (3)$$

of which the smallest positive root is  $\bar{\alpha} \simeq 0 \cdot 175$ , giving  $\bar{q}_{1,1} \simeq 1 \cdot 4$ . Substituting this in the formulae  $\bar{\omega}_1^2 = 4\bar{q}_{1,1}c^2/a^2e^2$  (see (4) § 16.23), we obtain [104]

$$\bar{\omega}_1 = 2 \cdot 96c/a = 1 \cdot 78c/b. \quad (4)$$

Thus  $\bar{\omega}_1/\omega_1 = 2 \cdot 96/1 \cdot 87 = 1 \cdot 58$ , so

$$\bar{\omega}_1 = 1 \cdot 58\omega_1. \quad (5)$$

Accordingly the pulsance of the first mode *transverse* to the major axis is 58 per cent. greater than that of the *longitudinal* mode. This is due to the minor axis being 40 per cent. shorter than the major axis, so the time taken for the disturbance to travel across the lake is less than that to travel along it. From (4) and Table 23 we see that  $\bar{\omega}_1$  is 3.3 per cent. less than that of the corresponding mode of a circular lake of radius  $b$ . It follows that if we commence with a circular lake and keep the length in the direction of the  $x$ -axis equal to  $2a$ , the effect of reducing the breadth is to raise the pulsance of the longitudinal oscillation, whereas an increase in breadth causes a decrease in pulsance. The order of the changes is small, however, even for large alterations in breadth.

For the modes of oscillation corresponding to  $Ce_0ce_0$ ,  $Ce_2ce_2$ ,  $Se_2se_2$ ,... the above method of calculating the values of  $q_{m,p}$ ,  $\bar{q}_{m,p}$

† See § 16.12 regarding symmetry about the axes.

fails owing to slowness of convergence of the series in powers of  $q$ . Under appropriate conditions formulae in § 12.41 may be used.

**16.30. Lake whose eccentricity  $e \rightarrow 1$ .** The plan of the lake is now a long narrow ellipse. Since  $\cosh \xi_0 = e^{-1}$ ,  $\xi_0 > \xi \rightarrow 0$ , so in (2) § 16.23, in order to obtain an approximate value of  $q_{1,1}$  for the gravest longitudinal mode, we may replace  $\sinh \xi_0$  by  $\xi_0$ . The tide height is given by

$$\zeta = C_1 C e_1(\xi, q_{1,1}) c e_1(\eta, q_{1,1}). \quad (1)$$

Then, with an accuracy adequate for illustration, we find that the equation for  $\alpha = q/8$  is

$$5.39\alpha^3 - 0.667\alpha^2 - 9\alpha + 1 = 0, \quad (2)$$

whose smallest positive root is  $\alpha \simeq 0.111$ , i.e.  $q_{1,1} = 0.888$ . Now  $\omega_1^2 = 4q_{1,1}c^2/a^2e^2$ , and since  $e \rightarrow 1$ , this value of  $q$  gives [104]

$$\omega_1 = 1.886c/a. \quad (3)$$

**16.31. Comparison of numerical results in §§ 16.23, 16.30.** The three sets of results are set out in Table 23. It is obvious therefrom that the breadth of the ellipse has little influence on the frequency of the slowest longitudinal mode. When the sides of the canal are straight and parallel, however,  $\omega_1 = \frac{1}{2}\pi c/a = 1.571c/a$ , which is 17 per cent. less than the pulsance when the eccentricity of the ellipse tends to unity (see third row of Table 23).

TABLE 23

<i>Plan of lake</i>	<i>Pulsance of slowest longitudinal mode (<math>\omega_1</math>)</i>
Circle of radius $a$	$1.84c/a$
Ellipse major axis $2a$ , minor axis $1.2a$	$1.87c/a$
Ellipse major axis $2a$ , eccentricity $e \rightarrow 1$	$1.886c/a$

The comparatively large difference may be attributed to curvature of the sides of the ellipse, which entails a diminution in cross-sectional area towards each end of the lake. This feature introduces reflection which is progressive and continuous from the centre towards the extremities of the major axis. Consequently the relative energy of the water per unit mass near the central part of the lake exceeds that in the straight-sided canal of uniform breadth.† Hence the ‘effective length’ of the elliptical lake is less than that of a uniform canal, and the lowest pulsance in the first case exceeds that

† Assuming the total energy to be equal in both cases.

in the second. It is of interest to remark that at any distance  $x$  from the centre, there is little difference in either the particle velocity in the  $x$  direction, or in the tide height in the two preceding cases.

**16.32. Surface elevation of water (tide height) in § 16.30.** This is expressed symbolically by

$$\zeta_1 = C_1 \text{Ce}_1(\xi, q_{1,1}) \text{ce}_1(\eta, q_{1,1}), \quad (1)$$

$C_1$  being an arbitrary constant,  $\cos \omega_1 t$  being omitted but tacitly assumed present. Since  $\xi \rightarrow 0$  and  $q_{1,1}$  is fixed,  $\text{Ce}_1$  is constant and, therefore,

$$\zeta_1 \propto \text{ce}_1(\eta, q_{1,1}). \quad (2)$$

Thus the elevation of the water surface is dependent upon the angular position  $\eta$ , but independent of  $\xi$ . Moreover, at any point distant  $x$  from the centre, but not too near to it, the displacement is substantially constant over the breadth of the lake.

From (2) § 2.17

$$\text{ce}_1(\eta, q_{1,1}) = A_1^{(1)} \cos \eta + A_3^{(1)} \cos 3\eta + A_5^{(1)} \cos 5\eta + \dots \quad (3)$$

Using tabular values [52, 95], we find the  $A$  corresponding to  $q_{1,1} = 0.888$  by interpolation. Substituting these in (3) yields

$$\text{ce}_1(\eta, 0.888) \simeq 0.990 \cos \eta - 0.123 \cos 3\eta + 0.005 \cos 5\eta. \quad (4)$$

In a canal of uniform breadth and length  $2a$ , the tide height for the slowest longitudinal mode at a distance  $x$  from the centre is proportional to  $\sin \pi x/2a$ . Taking  $\cos \eta = x/a$ , we get

$$\zeta \propto \sin \frac{1}{2}\pi(\cos \eta) = 2[J_1(\frac{1}{2}\pi)\cos \eta - J_3(\frac{1}{2}\pi)\cos 3\eta + J_5(\frac{1}{2}\pi)\cos 5\eta - \dots] \quad (5)$$

$$\propto 0.990 \cos \eta - 0.121 \cos 3\eta + 0.0039 \cos 5\eta. \quad (6)$$

Comparing (4), (6), the difference lies in the slightly larger coefficients of  $\cos 3\eta$ ,  $\cos 5\eta$  in the case of the elliptical lake where  $e \rightarrow 1$ . Consequently in passing from the right-hand ends of the lakes towards their centres, the tide heights calculated from (4), (6) are almost equal for all  $\eta$  in  $0 - \frac{1}{2}\pi$ . A rough idea of the shape of the water surface may be gleaned from the graph of  $\text{ce}_1(z, 2)$  in Fig. 1. When frictional loss is taken into account there is no significant difference in the tide heights of the water at corresponding points in the two cases considered.

**16.33. Pulsatances of modes corresponding to  $\text{Ce}_2$ ,  $\text{Ce}_3$ , ... when  $e \rightarrow 1$ .** In [53] it is shown that when  $\xi_0 \rightarrow 0$ , i.e.  $e \rightarrow 1$ , there is only one value of  $q > 0$  for which  $\text{Ce}'_m(\xi, q) = 0$ ,  $m \geq 1$ . Thus there

is only one mode of oscillation corresponding to each  $m$ . If  $q > q_{m,1}$  satisfied the pulsance equation, we should have  $Ce'_m(\xi, q_{m,p}) = 0$  for  $\xi < \xi_0$ , thereby entailing the existence of nodal ellipses. Since there is only one parametric zero, namely,  $q_{m,1}$ , there are no nodal ellipses associated with the modes of oscillation of an elliptical lake whose eccentricity  $e \rightarrow 1$ .

To calculate the roots of  $Ce'_m(\xi_0, q) = 0$ , we use a transcendental equation like (8) § 3.11, write  $2q$  for  $a$  on the l.h.s. and in the continued fraction,† and proceed to calculate  $q$  and the  $A$  as in § 3.12 et seq. The following results were obtained [54]:

$$q_{1,1} = 0.88982 \ 0 \text{ giving}$$

$$ce_1(\eta, q_{1,1}) = 0.99241 \cos \eta - 0.12288 \cos 3\eta + 0.00471 \cos 5\eta - 0.00009 \cos 7\eta + \dots; \quad (1)$$

$$q_{2,1} = 3.03907 \ 36 \text{ giving}$$

$$ce_2(\eta, q_{2,1}) = 0.39516 + 0.79032 \cos 2\eta - 0.24989 \cos 4\eta + 0.02552 \cos 6\eta - 0.00134 \cos 8\eta + 0.00004 \cos 10\eta - \dots; \quad (2)$$

$$q_{3,1} = 6.42586 \ 16 \text{ giving}$$

$$ce_3(\eta, q_{3,1}) = 0.71339 \cos \eta + 0.60237 \cos 3\eta - 0.35232 \cos 5\eta + 0.06370 \cos 7\eta - 0.00604 \cos 9\eta + 0.00036 \cos 11\eta - 0.00001 \cos 13\eta + \dots; \quad (3)$$

$$q_{4,1} = 11.04799 \ 28 \text{ giving}$$

$$ce_4(\eta, q_{4,1}) = 0.32544 + 0.65107 \cos 2\eta + 0.41535 \cos 4\eta - 0.42190 \cos 6\eta + 0.11561 \cos 8\eta - 0.01661 \cos 10\eta + 0.00151 \cos 12\eta - 0.00010 \cos 14\eta + 0.00001 \cos 16\eta - \dots; \quad (4)$$

$$q_{5,1} = 16.90474 \ 0 \text{ giving}$$

$$ce_5(\eta, q_{5,1}) = 0.61238 \cos \eta + 0.57615 \cos 3\eta + 0.23319 \cos 5\eta - 0.45463 \cos 7\eta + 0.17534 \cos 9\eta - 0.03485 \cos 11\eta + 0.00441 \cos 13\eta - 0.00039 \cos 15\eta + 0.00003 \cos 17\eta - \dots \quad (5)$$

The various series (1)–(5) exemplify (a) the rapid decrease in the numerical values of the coefficients beyond a certain term, (b) the remarks at the end of § 3.33.

Using the above values of  $q_{m,1}$ , the pulsances of the first five longitudinal modes of a lake whose eccentricity approaches unity were calculated, and are given in Table 24.

† This substitution is based on the result that as  $e \rightarrow 1$ ,  $a \rightarrow 2q$  [53].

TABLE 24

Mode of oscillation	Function	Value of $q_{m,1}$	Pulsatance $\omega_1$	$\omega_1$ for straight uniform canal
1	$ce_1$	0.88982 0	$1.8866c/a$	$1.5708..c/a \uparrow$
2	$ce_2$	3.03907 4	$3.4866c/a$	$3.1416..c/a$
3	$ce_3$	6.42586 2	$5.0699c/a$	$4.7124..c/a$
4	$ce_4$	11.04799 3	$6.6477c/a$	$6.2832..c/a$
5	$ce_5$	16.90474 0	$8.2231c/a$	$7.8540..c/a$

† The numbers are multiples of  $\frac{1}{4}\pi$ .

The tide ranges for several modes calculated by aid of (2)–(5) are portrayed in Figs. 34–7 [54, 104].

FIG. 34. Tide height  $\zeta$  in lowest symmetrical mode of water in elliptical lake. The broken line is for a canal of uniform breadth.

FIG. 35. Tide height  $\zeta$  in second asymmetrical mode of water in elliptical lake. The broken line is for a canal of uniform breadth.

**16.40. Transverse vibrational modes of gas in long hollow elliptical cylinder.** If  $\phi$  is the velocity potential at any point  $x, y$  in a cross-section, the differential equation of wave motion is

$$\frac{\partial^2 \phi}{\partial x^2} + \frac{\partial^2 \phi}{\partial y^2} + k_1^2 \phi = 0, \tag{1}$$

FIG. 36. Tide height  $\zeta$  in second symmetrical mode of water in elliptical lake. The broken line is for a canal of uniform breadth.

FIG. 37. Tide height  $\zeta$  in third asymmetrical mode of water in elliptical lake. The broken line is for a canal of uniform breadth.

where  $k_1 = \omega/c$ ,  $\omega = 2\pi \times \text{frequency}$ , and  $c$  is the velocity of sound waves in an unconfined atmosphere of the gas, of uniform density. If the inner surface of the cylinder on which the gas particles impinge is rigid, the velocity normal thereto is zero. Hence the particle velocity  $v = -(\partial\phi/\partial n) = 0$ ,  $n$  indicating the direction of the normal to the inner surface. Accordingly the problem is analytically similar to that of the elliptical lake studied in § 16.20 et seq., so the pulsation equations are those at (4), (5) § 16.21. When the ellipse degenerates to a circle the vibrational modes of the gas in a hollow circular cylinder are obtained. The pulsation equation is now (6) § 16.23. It is assumed that the cylinder is long enough for end effect to be neglected, or that practical conditions ensure absence of interference due to the ends of a short cylinder.

**16.50. Vibrational modes of elliptical plate.** Let  $\rho$  be the density,  $t$  the uniform thickness,  $\sigma$  Poisson's ratio  $< 1$ ,  $E$  Young's

modulus, and  $c^2 = Et^2/12\rho(1-\sigma^2)$ . Assume that  $\zeta$ , the displacement normal to the plane of the plate, varies as  $e^{i\omega t}$ . Then with  $k_1^4 = \omega^2/c^2$  it can be shown that the differential equation of motion of a homogeneous loss-free plate vibrating with small amplitude *in vacuo* is

$$\frac{\partial^4 \zeta}{\partial x^4} + \frac{\partial^4 \zeta}{\partial y^4} + \frac{2\partial^4 \zeta}{\partial x^2 \partial y^2} - k_1^4 \zeta = 0, \quad (1)$$

or 
$$\left( \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + k_1^2 \right) \left( \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} - k_1^2 \right) \zeta = 0. \quad (2)$$

Hence 
$$\frac{\partial^2 \zeta_1}{\partial x^2} + \frac{\partial^2 \zeta_1}{\partial y^2} + k_1^2 \zeta_1 = 0, \quad (3)$$

and 
$$\frac{\partial^2 \zeta_2}{\partial x^2} + \frac{\partial^2 \zeta_2}{\partial y^2} - k_1^2 \zeta_2 = 0. \quad (4)$$

By § 9.20, (3), (4) expressed in elliptical coordinates are, respectively,

$$\frac{\partial^2 \zeta_1}{\partial \xi^2} + \frac{\partial^2 \zeta_1}{\partial \eta^2} + 2k^2(\cosh 2\xi - \cos 2\eta)\zeta_1 = 0, \quad (5)$$

and 
$$\frac{\partial^2 \zeta_2}{\partial \xi^2} + \frac{\partial^2 \zeta_2}{\partial \eta^2} - 2k^2(\cosh 2\xi - \cos 2\eta)\zeta_2 = 0, \quad (6)$$

where  $2k = k_1 h = (\omega/c)^{1/2} h$ , giving  $q = \omega h^2/4c$ .

This analysis is valid for a variety of boundary conditions amongst which we may mention:

- 1°. Free everywhere.
- 2°. Clamped edge, centre free.
- 3°. Clamped edge, confocal elliptical hole at centre.
- 4°. Clamped edge, clamped at a central confocal ellipse.
- 5°. Clamped at a central confocal ellipse, edge free.

The solutions for all five cases must be periodic in  $\eta$ , with period  $\pi$  or  $2\pi$ . For reasons akin to those given in § 16.11 a formal solution of (5) in cases 1°, 2° is (omitting the time factor)

$$\zeta_1^{(m)} = C_m \text{Ce}_m(\xi, q) \text{ce}_m(\eta, q) + S_m \text{Se}_m(\xi, q) \text{se}_m(\eta, q). \quad (7)$$

For (6) we have

$$\zeta_2^{(m)} = \bar{C}_m \text{Ce}_m(\xi, -q) \text{ce}_m(\eta, -q) + \bar{S}_m \text{Se}_m(\xi, -q) \text{se}_m(\eta, -q). \quad (8)$$

Then  $\zeta^{(m)} = \zeta_1^{(m)} + \zeta_2^{(m)}$ , and the complete formal solution is

$$\begin{aligned} \zeta = \sum_{m=0}^{\infty} \{C_m \text{Ce}_m(\xi, q) \text{ce}_m(\eta, q) + \bar{C}_m \text{Ce}_m(\xi, -q) \text{ce}_m(\eta, -q)\} + \\ + \sum_{m=1}^{\infty} \{S_m \text{Se}_m(\xi, q) \text{se}_m(\eta, q) + \bar{S}_m \text{Se}_m(\xi, -q) \text{se}_m(\eta, -q)\}. \end{aligned} \quad (9)$$

When the centre of the plate is removed or clamped, the solutions  $Fey_m$ ,  $Gey_m$ ,  $Fek_m$ ,  $Gek_m$  must be included, so we have for cases 3°-5°:

$$\zeta_1^{(m)} = C_m Ce_m(\xi, q)ce_m(\eta, q) + F_m Fey_m(\xi, q)ce_m(\eta, q) + S_m Se_m(\xi, q)se_m(\eta, q) + G_m Gey_m(\xi, q)se_m(\eta, q) \quad (10)$$

and

$$\zeta_2^{(m)} = \bar{C}_m Ce_m(\xi, -q)ce_m(\eta, -q) + \bar{F}_m Fek_m(\xi, -q)ce_m(\eta, -q) + \bar{S}_m Se(\xi, -q)se_m(\eta, -q) + \bar{G}_m Gek_m(\xi, -q)se_m(\eta, -q). \quad (11)$$

The complete solution takes a form similar to (9).

**16.51. Clamped edge, centre free.** Consider those modes where the displacement is either symmetrical about both axes or about the minor axis only. The first necessitates a solution with  $ce_{2n}$ , and the second with  $ce_{2n+1}$  (see § 16.12), the  $se_m$  functions being inadmissible. The appropriate formal solution for the  $m$ th mode is, by (9) § 16.50,

$$\zeta^{(m)} = C_m Ce_m(\xi, q)ce_m(\eta, q) + \bar{C}_m Ce_m(\xi, -q)ce_m(\eta, -q). \quad (1)^\dagger$$

The boundary conditions are  $\zeta = d\zeta/d\xi = 0$  at the clamped edge where  $\xi = \xi_0$ . Using these in (1) leads to the two conditional equations

$$C_m Ce_m(\xi_0, q)ce_m(\eta, q) + \bar{C}_m Ce_m(\xi_0, -q)ce_m(\eta, -q) = 0 \quad (2)$$

and

$$C_m Ce'_m(\xi_0, q)ce_m(\eta, q) + \bar{C}_m Ce'_m(\xi_0, -q)ce_m(\eta, -q) = 0. \quad (3)$$

From (2), (3) we deduce that

$$[Ce_m(\xi_0, q)Ce'_m(\xi_0, -q) - Ce'_m(\xi_0, q)Ce_m(\xi_0, -q)]ce_m(\eta, q)ce_m(\eta, -q) = 0. \quad (4)$$

Hence we have the pulsantance equation

$$Ce_m(\xi_0, q)Ce'_m(\xi_0, -q) - Ce'_m(\xi_0, q)Ce_m(\xi_0, -q) = 0, \quad (5)$$

which may be written

$$\frac{d}{d\xi} [Ce_m(\xi, q)/Ce_m(\xi, -q)]_{\xi=\xi_0} = 0. \quad (6)$$

This equation is satisfied by  $q = q_{m,s}$ ,  $s = 1, 2, \dots$  and defines a system of confocal nodal ellipses  $0 < \xi \leq \xi_0$ . From (4) we have the equations defining a system of nodal hyperbolae, namely,

$$ce_m(\eta, q) = 0 \quad \text{and} \quad ce_m(\eta, -q) = 0. \quad (7)$$

† When  $m = 2n+1$ , and  $q < 0$ , in (1)-(7) write  $Se$ ,  $se$  for  $Ce$ ,  $ce$ : in (8), (9) write  $Ce$ ,  $ce$  for  $Se$ ,  $se$ . See [229].

Nodal ellipses and nodal hyperbolae coexist, being analogous to nodal circles and radii on a freely vibrating circular plate.

For modes in which the displacement is anti-symmetrical about the major axis or about both axes, the pulsance equation is

$$\text{Se}_m(\xi_0, q)\text{Se}'_m(\xi_0, -q) - \text{Se}'_m(\xi_0, q)\text{Se}_m(\xi_0, -q) = 0. \quad (8)$$

This defines a second system of confocal nodal ellipses. The equations for the accompanying system of nodal hyperbolae are

$$\text{se}_m(\eta, q) = 0 \quad \text{and} \quad \text{se}_m(\eta, -q) = 0. \quad (9)$$

Accordingly there is a double infinity of both classes of nodal pattern.

**16.52. Determination of  $q_{2n,s}$  in (6) § 16.51.** If  $q$  is small, the procedure in § 16.17 may be followed. For large values of  $q = k^2$  the asymptotic formula (3) § 11.42 may be used. Applying the relationship  $\text{Ce}_{2n}(\xi, -q) = (-1)^n \text{Ce}_{2n}(\frac{1}{2}\pi i + \xi, q)$  thereto, and selecting the real part, we obtain with  $\xi$  large enough

$$\text{Ce}_{2n}(\xi, -q) \sim C_{2n}[\cosh w_1 \cos \varpi + \sinh w_1 \sin \varpi]/2^{2n} \sinh \frac{1}{2}\xi, \quad (1)$$

where  $w_1 = 2k \cosh \xi$ ,  $\varpi \simeq (4n+1)\tan^{-1}(\tanh \frac{1}{2}\xi)$ . Thus by (1) above and (3) § 11.42

$$\frac{\text{Ce}_{2n}(\xi, q)}{\text{Ce}_{2n}(\xi, -q)} \sim \frac{\tanh \frac{1}{2}\xi \cos \chi}{2^{\frac{1}{2}} \cosh \chi_1}, \quad (2)$$

with  $\chi = 2k \sinh \xi - (4n+1)\tan^{-1}(\tanh \frac{1}{2}\xi)$

and  $\cosh \chi_1 = \cosh w_1 \cos \varpi + \sinh w_1 \sin \varpi$ .

Differentiating (2), as indicated in (6) § 16.51, leads to the pulsance equation

$$[\chi' \tan \chi + \chi'_1 \tanh \chi_1]_{\xi=\xi_0} = (\sinh 2\xi_0)^{-1},$$

or  $[\tan \chi + (\chi'_1/\chi') \tanh \chi_1]_{\xi=\xi_0} = (\chi' \sinh 2\xi)^{-1}_{\xi=\xi_0}$ . (3)

Now  $k$  is large by hypothesis, so when  $\xi_0$  is large enough the r.h.s. of (3) is very small,  $(\chi'_1/\chi') \tanh \chi_1 \simeq 1$ , and (3) approximates to

$$\tan \chi = -1 \quad \text{or} \quad \chi = s\pi - \frac{1}{4}\pi = (s - \frac{1}{4})\pi, \quad (4)$$

$s$  being an integer. This entails

$$2k \sinh \xi_0 = (s - \frac{1}{4})\pi + (4n+1)\tan^{-1}(\tanh \frac{1}{2}\xi_0). \quad (5)$$

Then for  $2k \sinh \xi_0 \rightarrow ke^{\xi_0}$  and  $\tanh \frac{1}{2}\xi_0 \rightarrow 1$ , we have

$$ke^{\xi_0} \simeq (s+n)\pi,$$

or  $k^2_{2n,s} = q_{2n,s} \simeq (s+n)^2 \pi^2 e^{-2\xi_0}$ . (6)

Equation (8) § 16.51 may be treated in a similar way.

**16.53. Transition to circular plate.** Using the degenerate forms of the modified Mathieu functions in Appendix I, both of the pulsance equations (5), (8) § 16.51 become

$$J_m(k_1 a)I'_m(k_1 a) - J'_m(k_1 a)I_m(k_1 a) = 0 \quad (k_1^2 = \omega/c), \quad (1)$$

which is the known result for the modes of a clamped circular plate of radius  $a$ . Using the dominant terms in the asymptotic formulæ for the Bessel functions, (1) gives

$$\cos(k_1 a - \frac{1}{4}\pi - \frac{1}{2}m\pi) + \sin(k_1 a - \frac{1}{4}\pi - \frac{1}{2}m\pi) = 0 \quad (2)$$

$$\text{or} \quad \tan(k_1 a - \frac{1}{4}\pi - \frac{1}{2}m\pi) = -1, \quad (3)$$

$$\text{so, if } s \text{ is an integer,} \quad k_1 a = (s + \frac{1}{2}m)\pi. \quad (4)$$

By Appendix I, as the bounding ellipse tends to a circle of radius  $a$ ,  $ke^{\xi_0} \rightarrow k_1 a$ , so if  $m = 2n$ , (4) above and (6) § 16.52 agree.

Since  $k_1^2 = \omega/c$ , (4) gives for the higher modes of vibration of a clamped circular plate of radius  $a$  and thickness  $t$

$$\omega = \frac{(s + \frac{1}{2}m)\pi t}{2a} \left[ \frac{E}{3\rho(1 - \sigma^2)} \right]^{\frac{1}{2}}. \quad (5)$$

Also by Appendix I, we see that (7), (8) § 16.50 degenerate to

$$\zeta_1^{(m)} = (C'_m \cos m\theta + S'_m \sin m\theta)J_m(k_1 r) \quad (6)$$

$$\text{and} \quad \zeta_2^{(m)} = (\bar{C}'_m \cos m\theta + \bar{S}'_m \sin m\theta)I_m(k_1 r), \quad (7)$$

the known forms for a circular plate.

### 16.60. Elliptical cylinder in viscous fluid [28, 116, 137, 154].

A long cylinder of elliptical cross-section† has its axis perpendicular to the plane of the paper. A viscous fluid, e.g. air, moves past the cylinder with undisturbed velocity  $U$  in a direction  $\theta$  to the major axis, as illustrated in Fig. 38. In the absence of viscosity the motion of the fluid would be irrotational. Owing, however, to friction between the surface of the cylinder and the fluid, by virtue of viscosity, the flow is accompanied by vortex motion, i.e. a perturbation is superimposed upon the irrotational motion. The problem is to determine the vorticity  $\zeta$  when the motion is steady. It is given by the expression

$$\zeta = \frac{\partial^2 \psi}{\partial x^2} + \frac{\partial^2 \psi}{\partial y^2}, \quad (1)$$

† The cylinder is many times longer than its major axis.

where  $\psi$  is the stream function. For *steady* motion the vorticity is known to be expressed by the differential equation

$$\frac{\partial^2 \zeta}{\partial x^2} + \frac{\partial^2 \zeta}{\partial y^2} - \frac{2}{\nu} \left( u \frac{\partial \zeta}{\partial x} + v \frac{\partial \zeta}{\partial y} \right) = 0, \quad (2)$$

FIG. 38. Illustrating cylinder in viscous fluid.

$u, v$  being the velocity components of the fluid parallel to the  $x$  and  $y$  axes, respectively,  $\frac{1}{2}\nu = \mu/\rho$ ,  $\mu$  the kinematic coefficient of viscosity,  $\rho$  the density of the undisturbed fluid. Then, if  $\phi$  is the velocity potential, we have

$$u = -\frac{\partial \psi}{\partial y} = -\frac{\partial \phi}{\partial x}, \quad (3)$$

$$v = \frac{\partial \psi}{\partial x} = -\frac{\partial \phi}{\partial y}. \quad (4)$$

For the undisturbed motion,† the velocity potential and stream function expressed in rectangular coordinates are

$$\phi_0 = -U(x \cos \theta + y \sin \theta), \quad (5)$$

$$\psi_0 = -U(y \cos \theta - x \sin \theta), \quad (6)$$

these satisfying (3), (4). Substituting from the two latter into (2) yields

$$\frac{\partial^2 \zeta}{\partial x^2} + \frac{\partial^2 \zeta}{\partial y^2} + \frac{2}{\nu} \left( \frac{\partial \phi}{\partial x} \frac{\partial \zeta}{\partial x} + \frac{\partial \phi}{\partial y} \frac{\partial \zeta}{\partial y} \right) = 0. \quad (7)$$

Applying formulae in § 9.20, (7) is transformed to elliptical coordinates and becomes

$$\frac{\partial^2 \zeta}{\partial \xi^2} + \frac{\partial^2 \zeta}{\partial \eta^2} + \frac{2}{\nu} \left( \frac{\partial \phi}{\partial \xi} \frac{\partial \zeta}{\partial \xi} + \frac{\partial \phi}{\partial \eta} \frac{\partial \zeta}{\partial \eta} \right) = 0. \quad (8)$$

† In the absence of friction between the fluid and the surface of the cylinder.

**16.61. Solution of (8) § 16.60.** Assume that the solution takes the form  $\zeta = e^{-\phi\nu}f(\xi, \eta)$ . Then since  $\frac{\partial^2\phi}{\partial\xi^2} + \frac{\partial^2\phi}{\partial\eta^2} = 0$ , we obtain

$$e^{-\phi\nu} \left\{ \frac{\partial^2 f}{\partial\xi^2} + \frac{\partial^2 f}{\partial\eta^2} - \frac{1}{\nu^2} \left[ \left( \frac{\partial\phi}{\partial\xi} \right)^2 + \left( \frac{\partial\phi}{\partial\eta} \right)^2 \right] f \right\} = 0. \quad (1)$$

Expressing (5), (6) § 16.60 in elliptical coordinates by aid of the substitutions  $x = h \cosh \xi \cos \eta$ ;  $y = h \sinh \xi \sin \eta$ , leads to

$$\phi_0 = -Uh(\cosh \xi \cos \eta \cos \theta + \sinh \xi \sin \eta \sin \theta) \quad (2)$$

$$\text{and} \quad \psi_0 = -Uh(\sinh \xi \sin \eta \cos \theta - \cosh \xi \cos \eta \sin \theta). \quad (3)$$

From these we find that  $\phi_0$  and  $\psi_0$  satisfy

$$\left( \frac{\partial\phi}{\partial\xi} \right)^2 + \left( \frac{\partial\phi}{\partial\eta} \right)^2 = \frac{U^2 h^2}{2} (\cosh 2\xi - \cos 2\eta). \quad (4)$$

Now (2), (3) are for undisturbed motion, so that if (4) is substituted into (1), a first approximation, based on Oseen's analysis, is

$$\frac{\partial^2 f}{\partial\xi^2} + \frac{\partial^2 f}{\partial\eta^2} - \frac{U^2 h^2}{2\nu^2} (\cosh 2\xi - \cos 2\eta) f = 0. \quad (5)$$

As in § 9.21 assume that  $f(\xi, \eta) = f_1(\xi)f_2(\eta)$ , and we get

$$f_2 \frac{d^2 f_1}{d\xi^2} + f_1 \frac{d^2 f_2}{d\eta^2} - \frac{U^2 h^2}{2\nu^2} (\cosh 2\xi - \cos 2\eta) f_1 f_2 = 0. \quad (6)$$

Dividing throughout by  $f_1 f_2$  yields

$$\frac{1}{f_1} \frac{d^2 f_1}{d\xi^2} - 2k^2 \cosh 2\xi = -\frac{1}{f_2} \frac{d^2 f_2}{d\eta^2} - 2k^2 \cos 2\eta = a, \quad \text{a constant,} \quad (7)$$

with  $U^2 h^2 / 2\nu^2 = 2k^2$ , or  $k^2 = U^2 h^2 / 4\nu^2$ . Then we get the two Mathieu equations

$$\frac{d^2 f_1}{d\xi^2} - (a + 2k^2 \cosh 2\xi) f_1 = 0, \quad (8)$$

$$\frac{d^2 f_2}{d\eta^2} + (a + 2k^2 \cos 2\eta) f_2 = 0. \quad (9)$$

**16.62. Conditions to be satisfied.** (a) As in § 16.11 the solution must be periodic in  $\eta$  with period  $\pi$  or  $2\pi$ ; (b) the amplitude of the motion must tend to zero as  $\xi \rightarrow +\infty$ ; (c) the circulation of the fluid at  $\xi = \infty$  must be bounded, otherwise the force on a finite length of cylinder would be infinite. (a) is satisfied if we choose  $ce_n(z, -q)$ ,  $se_n(z, -q)$  as the solutions of (9) § 16.61. Now

$$\zeta = e^{-\phi\nu} f_1(\xi) f_2(\eta), \quad (1)$$

and to fulfil (b),  $e^{-\phi\nu}f_1(\xi)$  must  $\rightarrow 0$  as  $\xi \rightarrow +\infty$ . Suppose we select the solutions  $\text{Fek}_n(\xi, -q)$ ,  $\text{Gek}_n(\xi, -q)$  for (8) § 16.61. Then, using their asymptotic forms from § 11.12 with  $\phi_0$  from (2) § 16.61, we must have

$$e^{-\phi\nu}f_1(\xi) \propto e^{2k(\cosh \xi \cos \eta \cos \theta + \sinh \xi \sin \eta \sin \theta) - k\xi} \sqrt{\left(\frac{1}{2ke\xi}\right)} \rightarrow 0. \quad (2)$$

From § 9.12,  $h \cosh \xi \sim r$ ,  $h \sinh \xi \sim r$ , as  $\xi \rightarrow +\infty$ ; also by § 2 Appendix I, since  $\frac{1}{2}h e^\xi \sim r$ ,  $k e^\xi \sim k_1 r$  as  $\xi \rightarrow +\infty$ . Writing  $2k = k_1 h$  and substituting in (2) we obtain

$$e^{-\phi\nu}f_1(\xi) \propto \frac{e^{k_1 r (\cos(\eta - \theta) - 1)}}{\sqrt{(2k_1 r)}}. \quad (3)$$

Now  $\{\cos(\eta - \theta) - 1\} < 0$  except for  $(\eta - \theta) = 0$  when it vanishes. Hence (3) tends to zero as  $r \rightarrow +\infty$ , and, therefore, as  $\xi \rightarrow +\infty$ . Accordingly a solution of the form

$$\zeta = e^{-\phi\nu} \left\{ \sum_{n=0}^{\infty} C_n \text{Fek}_n(\xi, -q) \text{ce}_n(\eta, -q) + \sum_{n=1}^{\infty} D_n \text{Gek}_n(\xi, -q) \text{se}_n(\eta, -q) \right\} \quad (4)$$

complies with conditions (a), (b). We shall now demonstrate that a modification of (4) is necessary, in order that condition (c) may be satisfied.

**16.63. Circulation of fluid as  $\xi \rightarrow +\infty$  [116].** We shall evaluate the difference in circulation of fluid over the ring defined by the confocal ellipses  $\xi = \xi_1$  and  $\xi = \xi_2$  as  $\xi_2 \rightarrow +\infty$ , which arises from one term in (4) § 16.62. We take the term  $C_n e^{-\phi\nu} \text{Fek}_n(\xi, -q) \text{ce}_n(\eta, -q)$ , and the circulation is proportional to

$$\iint e^{-\phi\nu} \text{Fek}_n(\xi, -q) \text{ce}_n(\eta, -q) ds_1 ds_2, \quad (1)$$

where  $ds_1, ds_2$  are elemental arcs, as defined in § 9.12, the integration extending over the ring. From § 9.12, when  $\xi$  is large enough,  $ds_1 ds_2 \sim r dr d\eta$ , so using (3) § 16.62 and the series for  $\text{ce}_n(\eta, -q)$ , (1) may be written

$$I_n = \text{const.} \int_{r_1}^{r_2} e^{-k_1 r} \chi_n dr \int_0^{2\pi} e^{k_1 r \cos(\eta - \theta)} \left[ \sum_{m=0}^{\infty} (-1)^m A_m^{(n)} \cos m\eta \right] d\eta, \quad (2)^\dagger$$

† For  $\text{ce}_{2n}(\eta, -q)$ ,  $A_m^{(n)} = A_{2m}^{(2n)}$ , and for  $\text{ce}_{2n+1}(\eta, -q)$ ,  $A_m^{(n)} = B_{2m+1}^{(2n+1)}$ .

where  $r_1$  corresponds to  $\xi_1$ ,  $r_2$  to  $\xi_2$ , and

$$\chi_n = 1 + \frac{(4a_n-1)}{8k_1 r} + \frac{(4a_n-1)(4a_n-9)}{2!(8k_1 r)^2} + \frac{(4a_n-1)\dots(4a_n-25)}{3!(8k_1 r)^3} + \dots, \quad (3)$$

which is the series part of the asymptotic expansion of  $\text{Fek}_n(z, -q)$  in (10) § 11.23, if the term in  $k^4$  in (8) § 11.20 is neglected.

Now

$$\begin{aligned} e^{k_1 r \cos(\eta-\theta)} \cos m\eta &= \left\{ I_0(k_1 r) + 2 \sum_{p=1}^{\infty} I_p(k_1 r) \cos p(\eta-\theta) \right\} \cos m\eta \\ &= I_0(k_1 r) \cos m\eta + \sum_{p=1}^{\infty} I_p(k_1 r) [\cos\{\eta(p+m)-p\theta\} + \\ &\quad + \cos\{\eta(p-m)-p\theta\}]. \quad (4) \end{aligned}$$

Using (4) in (2), all the integrals vanish except when  $p = m$ , so

$$\int_0^{2\pi} e^{k_1 r \cos(\eta-\theta)} \cos m\eta \, d\eta = 2\pi I_m(k_1 r) \cos m\theta. \quad (5)$$

But when  $k_1 r$  is very large [ref. 202, p. 163]

$$I_m(k_1 r) \sim \frac{e^{k_1 r}}{\sqrt{(2\pi k_1 r)}} \left\{ 1 - \frac{(4m^2-1)}{8k_1 r} + \frac{(4m^2-1)(4m^2-9)}{2!(8k_1 r)^2} - \dots \right\}. \quad (6)$$

Substituting from (5), (6) into (2) yields

$$\begin{aligned} I_n &= \text{const.} \int_{r_1}^{r_2} \chi_n \left[ \sum_{m=0}^{\infty} (-1)^m A_m^{(n)} \cos m\theta \times \right. \\ &\quad \left. \times \left\{ 1 - \frac{(4m^2-1)}{8k_1 r} + \frac{(4m^2-1)(4m^2-9)}{2!(8k_1 r)^2} - \dots \right\} \right] dr. \quad (7) \end{aligned}$$

Since  $\sum_{m=0}^{\infty} (-1)^{s+m} A_m^{(n)} m^{2s} \cos m\theta = (d^{2s}/d\theta^{2s})[\text{ce}_n(\theta, -q)]$ , the integrand of (7) may be written

$$\chi_n \left[ \text{ce}_n + \frac{1}{8k_1 r} (\text{ce}_n + 4\text{ce}_n') + \frac{1}{2!(8k_1 r)^2} (16\text{ce}_n'' + 40\text{ce}_n' + 9\text{ce}_n) + \dots \right]. \quad (8)$$

Designating the coefficients of  $1/r$ ,  $1/r^2$ , ... in (3), (8) by  $\alpha_1$ ,  $\alpha_2$ , ...,  $\beta_1$ ,  $\beta_2$ , ..., respectively, (8) yields

$$\begin{aligned} &(1 + \alpha_1 r^{-1} + \alpha_2 r^{-2} + \dots)(\beta_0 + \beta_1 r^{-1} + \beta_2 r^{-2} + \dots) \\ &= \beta_0 + (\alpha_1 \beta_0 + \beta_1) r^{-1} + (\alpha_2 \beta_0 + \alpha_1 \beta_1 + \beta_2) r^{-2} + \dots \quad (9) \end{aligned}$$

Inserting this in (7) and integrating with respect to  $r$  leads to

$$I_n = \text{const.} \left\{ \beta_0(r_2 - r_1) + (\alpha_1 \beta_0 + \beta_1) \log \frac{r_2}{r_1} + \right. \\ \left. + (\alpha_2 \beta_0 + \alpha_1 \beta_1 + \beta_2) \left( \frac{1}{r_1} - \frac{1}{r_2} \right) + \dots \right\} \quad (10)$$

$$= \Lambda_n \beta_0 \left\{ (r_2 - r_1) + (\alpha_1 + \beta_1/\beta_0) \log(r_2/r_1) + \right. \\ \left. + (\alpha_2 + \alpha_1 \beta_1/\beta_0 + \beta_2/\beta_0) \left( \frac{1}{r_1} - \frac{1}{r_2} \right) + \dots \right\}. \quad (11)$$

Since (11)  $\rightarrow \infty$  with  $r_2$ , it follows that the presence of a term of the form  $e^{-\phi/\nu} C_n \text{Fek}_n(\xi, -q) \text{ce}_n(\eta, -q)$ , as in (4) § 16.62, introduces an infinite circulation as  $r_2 \rightarrow \infty$ , which is physically impossible. It is necessary, therefore, to modify the term in question to give a finite solution.

Only the first two terms in (11) yield infinities, so we consider these and disregard the remainder of the series, because it is convergent and finite. Then

$$\alpha_1 + \beta_1/\beta_0 = \frac{1}{8k_1} \left\{ (4a_n - 1) + 1 + \frac{4\text{ce}_n''}{\text{ce}_n} \right\} = \frac{1}{2k_1} (a_n + \text{ce}_n''/\text{ce}_n). \quad (12)$$

Now  $\text{ce}_n'' + (a_n + 2k^2 \cos 2\theta) \text{ce}_n = 0$ , so that

$$a_n + \text{ce}_n''/\text{ce}_n = -2k^2 \cos 2\theta, \quad (13)$$

which gives

$$(\alpha_1 + \beta_1/\beta_0) = -\frac{k^2}{k_1} \cos 2\theta = -\frac{Uh^2}{4\nu} \cos 2\theta. \quad (14)$$

Using (14) in (11), if  $\theta$  is fixed—as it would be in practice—with  $\beta_0 = \text{ce}_n$  or  $\text{ce}_{n+1}$ , we get

$$I_n/\Lambda_n \text{ce}_n \\ = \left\{ (r_2 - r_1) - \frac{Uh^2}{4\nu} \cos 2\theta \log r_2/r_1 + L_n \text{ (finite as } r_2 \rightarrow \infty) \right\}, \quad (15)$$

$$I_{n+1}/\Lambda_{n+1} \text{ce}_{n+1} \\ = \left\{ (r_2 - r_1) - \frac{Uh^2}{4\nu} \cos 2\theta \log r_2/r_1 + L_{n+1} \text{ (finite as } r_2 \rightarrow \infty) \right\}. \quad (16)$$

Although both (15), (16)  $\rightarrow \infty$  with  $r_2$ , their difference

$$(I_n/\Lambda_n \text{ce}_n) - (I_{n+1}/\Lambda_{n+1} \text{ce}_{n+1}) = L_n - L_{n+1}, \quad (17)$$

is finite. Hence the first part of the solution (4) § 16.62 must be taken in the form

$$Fk_{n,n+1} = e^{-\phi/\nu} [C_n Fek_n ce_n - C_{n+1} Fek_{n+1} ce_{n+1}], \quad (18)$$

where  $C_n, C_{n+1}$  are constants whose ratio is chosen to annul the first two terms at (15), (16).

The results for the second part of the solution at (4) § 16.62, namely,  $e^{-\phi/\nu} D_n Gek_n se_n$  are identical in form with those above, except that sin is written for cos, and se for ce. Thus to preserve finite circulation we take

$$Gk_{n,n+1} = e^{-\phi/\nu} [D_n Gek_n se_n - D_{n+1} Gek_{n+1} se_{n+1}]. \quad (19)$$

Finally the complete solution which satisfies conditions (a), (b), (c) in § 16.62 is given by

$$\zeta = e^{-\phi/\nu} \left\{ \sum_{n=0}^{\infty} Fk_{n,n+1} + \sum_{n=1}^{\infty} Gk_{n,n+1} \right\}. \quad (20)$$

The arbitrary constants  $C, D$  in (18), (19) are found from the boundary conditions as usual.

## XVII

### ELECTRICAL AND THERMAL DIFFUSION

**17.10. Eddy current loss in core of solenoid.** When a sinusoidal current flows in a solenoid having a metal core of elliptical cross-section, the varying magnetic field induces eddy currents therein, the core behaving like the secondary winding of a transformer. To calculate the loss arising from these currents we assume that:

1. The current in the winding is everywhere in phase.
2. The core is a uniform metal bar of elliptical cross-section, having resistivity  $\rho$  and permeability  $\mu$ , the latter being independent of  $H$  the magnetizing force.
3. The uniformly wound solenoid of  $n$  turns is long compared with its cross-sectional dimensions.
4.  $H$  is uniform at the curved surface of the bar.

*Differential equation for  $H$ .* It can be shown that, in rectangular coordinates, the equation for  $H$  at any point  $(x, y)$  of a cross-section of the bar is [167]

$$\frac{\partial^2 H}{\partial x^2} + \frac{\partial^2 H}{\partial y^2} - \frac{4\pi\mu}{\rho} \frac{\partial H}{\partial t} = 0. \quad (1)$$

If  $H = H_1 e^{i\omega t}$ ,  $\partial H / \partial t = i\omega H$ , and (1) becomes

$$\frac{\partial^2 H}{\partial x^2} + \frac{\partial^2 H}{\partial y^2} - i \left( \frac{4\pi\mu\omega}{\rho} \right) H = 0. \quad (2)$$

Introducing elliptical coordinates as in § 9.20, this equation is transformed to

$$\frac{\partial^2 H}{\partial \xi^2} + \frac{\partial^2 H}{\partial \eta^2} + 2k^2 (\cosh 2\xi - \cos 2\eta) H = 0, \quad (3)$$

where  $4k^2 = k_1^2 h^2 = -i\hbar^2 (4\pi\mu\omega/\rho)$ . Thus  $k^2$  is negative imaginary and  $2k = i\hbar m$ , with  $m = (4\pi\mu\omega/\rho)^{\frac{1}{2}}$ . Then by § 9.21 a suitable solution of (3) is  $H = \chi(\xi)\phi(\eta)$ ,  $\chi$  being a solution of

$$\frac{d^2 \chi}{d\xi^2} - (a - 2k^2 \cosh 2\xi) \chi = 0, \quad (4)$$

and  $\phi$  a solution of

$$\frac{d^2 \phi}{d\eta^2} + (a - 2k^2 \cos 2\eta) \phi = 0. \quad (5)$$

**17.11. Physical conditions.** The distribution of  $H$  round any confocal ellipse in a cross-section of the core is symmetrical about the major and minor axes. Also  $H$  is single-valued and periodic in  $\eta$  with period  $\pi$ . Hence  $\phi$  must be a multiple of  $\text{ce}_{2n}(\eta, q)$ . Further, to satisfy (b) § 16.11 the solution

$$\chi = F\text{e}_{2n}(\xi, q)$$

must be excluded. Thus  $\text{Ce}_{2n}(\xi, q)\text{ce}_{2n}(\eta, q)$  is the only admissible type of solution of (3) § 17.10. Accordingly at any point  $(\xi, \eta)$  of the cross-section we have

$$H = \sum_{n=0}^{\infty} C_{2n} \text{Ce}_{2n}(\xi, q)\text{ce}_{2n}(\eta, q), \quad (1)$$

the constants  $C_{2n}$  being determinable from the boundary conditions.

**17.12. Determination of  $C_{2n}$  in (1) § 17.11.** At the surface of the core,  $H = H_0$ , a constant given by  $4\pi n I_{r.m.s.}/l$ ,  $I_{r.m.s.}$  being the root mean square value of the current† and  $l$  the axial length of the solenoid. Thus at  $\xi = \xi_0$

$$H_0 = \sum_{n=0}^{\infty} C_{2n} \text{Ce}_{2n}(\xi_0, q)\text{ce}_{2n}(\eta, q). \quad (1)$$

Multiplying both sides of (1) by  $\text{ce}_{2n}(\eta, q)$  and integrating with respect to  $\eta$  from 0 to  $2\pi$ , we get

$$\begin{aligned} H_0 \int_0^{2\pi} \text{ce}_{2n}(\eta, q) d\eta &= C_{2n} \text{Ce}_{2n}(\xi_0, q) \int_0^{2\pi} \text{ce}_{2n}^2(\eta, q) d\eta \\ &= C_{2n} \text{Ce}_{2n}(\xi_0, q) \mathfrak{L}_{2n}, \end{aligned} \quad (2)$$

where  $\mathfrak{L}_{2n} = \int_0^{2\pi} \text{ce}_{2n}^2(\eta, q) d\eta$ , the other integrals vanishing by virtue of orthogonality.‡ The value of the first integral in (2) is  $2\pi H_0 A_0^{(2n)}$ , it being understood that since  $k^2$  is negative imaginary, the  $A$  in the series for  $\text{ce}_{2n}(\eta, q)$  are complex (see § 3.40 et seq.). Thus we obtain

$$C_{2n} = 2\pi H_0 A_0^{(2n)} / \text{Ce}_{2n}(\xi_0, q) \mathfrak{L}_{2n}. \quad (3)$$

Hence by (1) § 17.11, (3) the magnetizing force at any point  $(\xi, \eta)$  of a core-section is given by

$$H_{\xi, \eta} = 2\pi H_0 \sum_{n=0}^{\infty} A_0^{(2n)} \text{Ce}_{2n}(\xi, q)\text{ce}_{2n}(\eta, q) / \mathfrak{L}_{2n} \text{Ce}_{2n}(\xi_0, q). \quad (4)$$

Since all quantities under the  $\sum$  sign are complex, so also is  $H_{\xi, \eta}$ , in general.

† The r.m.s. value is selected merely for convenience, since it is used in § 17.20.

‡ When  $q = k^2$  is real the value of the integral is  $\pi$ . In (2),  $q$  is negative imaginary.

**17.13. Transition to circular cross-section.** By Appendix I  $Ce_{2n}(\xi, q) \rightarrow p'_{2n} J_{2n}(k_1 r)$ ,  $Ce_{2n}(\xi_0, q) \rightarrow p'_{2n} J_{2n}(k_1 a)$ ,  $a$  being the radius of the core, while  $ce_{2n}(\eta, q) \rightarrow \cos 2n\theta$ ,  $n \geq 1$ ,  $ce_0(\eta, q) \rightarrow A_0^{(0)} = (2)^{-\frac{1}{2}}$ ,  $A_0^{(2n)} \rightarrow 0$ ,  $n \geq 1$ . Also  $\Omega_{2n} \rightarrow \int_0^{2\pi} \cos^2 2n\theta d\theta = \pi$ . Hence all terms of (4) § 17.12 vanish except when  $n = 0$ , and for a core of circular section we get

$$H = H_0 J_0(k_1 r) / J_0(k_1 a). \quad (1)$$

Now  $k_1 = i^{\frac{1}{2}} m$ , so (1) becomes

$$H = H_0 J_0(i^{\frac{1}{2}} m r) / J_0(i^{\frac{1}{2}} m a). \quad (2)$$

Expressing the  $J$  function in polar form, with

$$J_\nu(i^{\frac{1}{2}} z) = \text{ber}_\nu z + i \text{bei}_\nu z = M_\nu(z) e^{i\theta_\nu(z)},$$

leads to

$$H = H_0 \frac{M_0(mr)}{M_0(ma)} e^{i[\theta_0(mr) - \theta_0(ma)]}. \quad (3)$$

$M_0(z)$ ,  $\theta_0(z)$  are tabulated in reference [202].

**17.14. Total flux in elliptical core.** This is found by integrating  $\mu H$  over a cross-section. Thus the total flux is, with  $k_1 = i^{\frac{1}{2}} m$ ,

$$\Phi = \mu \int H dA = -\frac{\mu}{k_1^2} \iint \left( \frac{\partial^2 H}{\partial x^2} + \frac{\partial^2 H}{\partial y^2} \right) dx dy, \quad (1)$$

by (2) § 17.10. Now if  $n$  is the outward normal and  $ds$  an elemental surface arc, (1) may be written

$$\Phi = -\frac{\mu}{k_1^2} \oint \frac{\partial H}{\partial n} ds = -\frac{\mu}{k_1^2} \int_0^{2\pi} \frac{\partial H}{\partial \xi} d\eta, \quad (2)$$

by virtue of the relationships  $ds = l_1 d\eta$ ,  $\partial n = l_1 \partial \xi$  in § 9.12. Substituting in (2) for  $H$  from (4) § 17.12 leads to

$$\Phi = -\frac{2\pi\mu H_0}{k_1^2} \sum_{n=0}^{\infty} \frac{A_0^{(2n)} Ce'_{2n}(\xi, q)}{\Omega_{2n} Ce_{2n}(\xi_0, q)} \int_0^{2\pi} ce_{2n}(\eta) d\eta, \quad (3)$$

$$= -\frac{4\pi^2\mu H_0}{k_1^2} \sum_{n=0}^{\infty} \frac{[A_0^{(2n)}]^2 Ce'_{2n}(\xi, q)}{\Omega_{2n} Ce_{2n}(\xi_0, q)}. \quad (4)$$

This represents the total flux within an ellipse defined by  $\xi < \xi_0$ . The total core flux is (4) with  $\xi_0$  for  $\xi$  in the numerator.

**17.15. Transition to circular cross-section.** By aid of Appendix I, (4) § 17.14 degenerates to the form

$$\Phi = -\frac{2\pi a\mu H_0}{k_1} \frac{J'_0(k_1 a)}{J_0(k_1 a)} = \frac{2\pi a\mu H_0}{mi^{\frac{1}{2}}} \frac{J_1(i^{\frac{1}{2}}ma)}{J_0(i^{\frac{1}{2}}ma)} \quad (1)$$

$$= \pi a^2 \mu H_0 \left[ \frac{2}{ma} \frac{M_1(ma)}{M_0(ma)} \right] e^{i[\theta_1(ma) - \theta_0(ma) - \frac{1}{2}\pi]}. \quad (2)$$

$M_0, \theta_0, M_1, \theta_1$  are tabulated in reference [202].

**17.20. Effective resistance  $R_e$  and effective inductance  $L_e$  due to core.** If  $I_{r.m.s.}$  is the root mean square value of the current in the solenoid, the p.d. across its ends is  $E_{r.m.s.} = (R_e + i\omega L_e)I_{r.m.s.}$ , so

$$I_{r.m.s.} = E_{r.m.s.} \left( \frac{R_e - i\omega L_e}{R_e^2 + \omega^2 L_e^2} \right) = \frac{E_{r.m.s.}}{Z_e^2} (R_e - i\omega L_e). \quad (1)$$

Accordingly we assume that  $I_{r.m.s.}$  has two components in phase quadrature. One of these causes a flux  $\Phi_e$  (equal but of opposite phase to that arising from eddy currents induced in the core) such that  $n d\Phi_e/dt = R_e I_{r.m.s.}$ . Thus the core loss is given by

$$R_e I_{r.m.s.}^2 = n \frac{d\Phi_e}{dt} I_{r.m.s.}. \quad (2)$$

Substituting  $H_0 = 4\pi n I_{r.m.s.}/l$  in (4) § 17.14 the total r.m.s. core flux is

$$\Phi = -\frac{16\pi^3 \mu n I_{r.m.s.}}{k_1^2 l} \sum_{n=0}^{\infty} \frac{[A_0^{(2n)}]^2 \text{Ce}'_{2n}(\xi_0, q)}{\Omega_{2n} \text{Ce}_{2n}(\xi_0, q)}. \quad (3)$$

$\Phi_e$  is the real part of (3), so if the flux varies as  $e^{i\omega t}$ , the core loss is, by (2), (3),

$$P = n \frac{d\Phi_e}{dt} I_{r.m.s.} = -\frac{16\pi^3 \mu \omega n^2 I_{r.m.s.}^2}{l} \text{Real} \left[ i \sum_{n=0}^{\infty} \frac{[A_0^{(2n)}]^2 \text{Ce}'_{2n}(\xi_0, q)}{k_1^2 \Omega_{2n} \text{Ce}_{2n}(\xi_0, q)} \right]. \quad (4)$$

Substituting  $k_1 = i^{\frac{1}{2}}m$  in (4), the power dissipated in the core is represented by

$$P = \frac{16\pi^3 \mu \omega n^2}{m^2 l} I_{r.m.s.}^2 \text{Real} \left[ \sum_{n=0}^{\infty} \frac{[A_0^{(2n)}]^2 \text{Ce}'_{2n}(\xi_0, q)}{\Omega_{2n} \text{Ce}_{2n}(\xi_0, q)} \right]. \quad (5)$$

Since  $P = R_e I_{r.m.s.}^2$ , the effective resistance due to the metal core is given by (5), if  $I_{r.m.s.}^2$  is omitted.

The so-called 'imaginary' power or energy per unit time stored in

the solenoid and restored to the power source periodically is found by similar analysis, using the imaginary part of (3), to be

$$\omega L_e I_{r.m.s.}^2 = \frac{16\pi^3 \mu \omega n^2}{m^2 l} I_{r.m.s.}^2 \operatorname{Imag} \left[ \sum_{n=0}^{\infty} \frac{[A_0^{(2n)}]^2 \operatorname{Ce}'_{2n}(\xi_0, q)}{\Omega_{2n} \operatorname{Ce}_{2n}(\xi_0, q)} \right]. \quad (6)$$

Hence the effective inductance of the solenoid due to the metal core alone is given by (6), provided  $\omega I_{r.m.s.}^2$  is omitted.

**17.21. Transition to circular cross-section.** By § 2 Appendix I we find that

$$\sum_{n=0}^{\infty} \frac{[A_0^{(2n)}]^2 \operatorname{Ce}'_{2n}(\xi_0, q)}{\Omega_{2n} \operatorname{Ce}_{2n}(\xi_0, q)} \rightarrow -\frac{k_1 a J_1(k_1 a)}{2\pi J_0(k_1 a)}, \quad (1)$$

so with  $k_1^2 = -im^2$ , (5) § 17.20 degenerates to

$$P = \frac{8\pi^2 \mu \omega a n^2}{ml} I_{r.m.s.}^2 \operatorname{Real} \left[ \frac{J_1(i^{\frac{1}{2}} m a)}{J_0(i^{\frac{1}{2}} m a)} e^{-i\pi i} \right] \quad (2)$$

$$= \frac{8\pi^2 \mu \omega a n^2}{ml} I_{r.m.s.}^2 \frac{M_1(ma)}{M_0(ma)} \cos(\theta_1 - \theta_0 - \tfrac{1}{2}\pi). \quad (3)$$

The effective resistance is given by (3), devoid of  $I_{r.m.s.}^2$ . In a similar way (6) § 17.20 degenerates to

$$L_e = \frac{8\pi^2 \mu a n^2}{ml} \frac{M_1(ma)}{M_0(ma)} \sin(\theta_1 - \theta_0 - \tfrac{1}{2}\pi). \quad (4)$$

**17.30. Resistance of long straight conductors of elliptical and rectangular section to high-frequency alternating currents.** At sufficiently high frequencies the current is confined mainly to a surface layer of the conductor, and the current density is negligible *within* the conductor. Thus the component of magnetic force normal to the surface tends to evanescence, and the magnetic force may be assumed wholly tangential thereto. It follows that, at the surface, the vector potential is constant and satisfies the same conditions as the scalar potential. Consequently the surface distribution of current density is identical with that of an electrostatic charge. The total current flowing axially through the conductor *corresponds* to the total surface charge [169].

**17.31. Formula for charge and current density.** We have now to find a formula for the charge at any point on the cylinder, bearing in mind that the surface potential  $\phi$  is constant. Using

elliptical coordinates  $(\xi, \eta)$ —see Fig. 39A—the potential function constant on the surface is, apart from a constant multiplier,

$$\phi = \xi \quad \text{at} \quad \xi = \xi_0. \quad (1)$$

FIG. 39. (A) Illustrating conductor of elliptical cross-section foci  $F_1, F_2$ . The hyperbola determines the coordinate  $\eta$  at the surface where  $\xi = \xi_0$ .

FIG. 39. (B) Ellipse having same area and axes ratio as rectangular section.

Now the charge at any point  $P$  whose coordinates are  $(\xi_0, \eta)$  is

$$\sigma_1 = K_1 d\phi/dn, \quad (2)$$

where  $K_1$  is a constant and  $n$  denotes the direction of the normal to the surface. By § 9.12,  $dn = h(\cosh^2 \xi_0 - \cos^2 \eta)^{1/2} d\xi$ , so from (1), (2)

$$\sigma_1 = K_1 \left( \frac{d\phi}{d\xi} \right) \frac{d\xi}{dn} = K_1 / h (\cosh^2 \xi_0 - \cos^2 \eta)^{1/2}. \quad (3)$$

(3) is proportional to the charge at any surface point  $(\xi_0, \eta)$ . Since  $\xi_0$  is constant,  $\sigma_1$  is a maximum when  $\eta = 0, \pi$  at the ends of the major axis. It is a minimum at the ends of the minor axis, where

$\eta = \frac{1}{2}\pi, \frac{3}{2}\pi$ . The values of  $\sigma_1$  at these respective points are

$$\sigma_{1(\max)} = K_1/h(\cosh^2\xi_0 - 1)^{\frac{1}{2}} = K_1/(a^2 - h^2)^{\frac{1}{2}} \quad (4)$$

and 
$$\sigma_{1(\min)} = K_1/h \cosh^2\xi_0 = K_1/a. \quad (5)$$

Using  $\sigma$  for current density, the magnetic force tangential to the surface at  $(\xi_0, \eta)$  is, with an appropriate multiplier  $K$  [169],

$$H_t = 4\pi\sigma = 4\pi K/h(\cosh^2\xi_0 - \cos^2\eta)^{\frac{1}{2}}. \quad (6)$$

**17.32. Power loss.** When  $H_t$  varies sinusoidally at high-frequency, it is shown in § 18.53 that the power loss per unit *surface* area of a conductor of unit permeability is  $(1/8\pi)H_t^2(\rho f)^{\frac{1}{2}}$ , where  $\rho$  = resistivity,  $f$  = frequency,  $H_t$  is the r.m.s. value, and the radius of curvature does not vanish at any point on the surface. The length of an elemental arc on the surface of the conductor (Fig. 17) is by § 9.12

$$ds = h(\cosh^2\xi_0 - \cos^2\eta)^{\frac{1}{2}} d\eta. \quad (1)$$

Thus the power loss over the periphery, per unit axial length, is, by (1) above and (6) § 17.31,

$$P = \frac{(\rho f)^{\frac{1}{2}}}{8\pi} \int H_t^2 ds = 8\pi K^2(\rho f)^{\frac{1}{2}} \int_0^{\frac{1}{2}\pi} d\eta/h(\cosh^2\xi_0 - \cos^2\eta)^{\frac{1}{2}}. \quad (2)$$

Now  $h \cosh \xi_0 = a$ , the semi-major axis, while  $(\cosh \xi_0)^{-1} = e$ , the eccentricity of the bounding ellipse. Accordingly (2) may be written

$$P = \frac{8\pi K^2(\rho f)^{\frac{1}{2}}}{a} \int_0^{\frac{1}{2}\pi} d\eta/(1 - e^2 \cos^2\eta)^{\frac{1}{2}} \quad (3)$$

$$= \frac{8\pi K^2(\rho f)^{\frac{1}{2}}}{a} F(e, \tfrac{1}{2}\pi) \quad (4)$$

[169], where  $F$  is a complete elliptic integral of the first kind with modulus  $e$ . The total current in the conductor corresponds to the total charge on unit length, i.e.

$$\int \sigma ds = K \int_0^{2\pi} d\eta = 2\pi K. \quad (5)$$

Hence the resistance per unit length of conductor to high-frequency alternating current is, by (4), (5),

$$R_{a.c.} = P/4\pi^2 K^2 = \frac{2(\rho f)^{\frac{1}{2}}}{\pi a} F(e, \tfrac{1}{2}\pi). \quad (6)$$

**17.33. Ratio  $R_{a.c.}/R_{d.c.}$ .** The resistance to a constant unidirectional current is

$$R_{d.c.} = \rho/\pi ab \quad (1)$$

per unit length of conductor. Thus by (1) and (6) § 17.32 we have

$$R_{a.c.}/R_{d.c.} = 2b(f/\rho)^{\frac{1}{2}} F(e, \frac{1}{2}\pi). \quad (2)$$

When the eccentricity  $e \rightarrow 1$ , it can be shown that [215]

$$F(e, \frac{1}{2}\pi) \simeq \log_e 4a/b. \quad (3)$$

Hence for an ellipse with  $a/b \gg 1$ , (2) may be written

$$R_{a.c.}/R_{d.c.} \simeq 2b(f/\rho)^{\frac{1}{2}} \log_e(4a/b). \quad (4)$$

When  $e \rightarrow 0$  the ellipse degenerates to a circle,  $F(e, \frac{1}{2}\pi) \rightarrow \frac{1}{2}\pi$ , and (2) becomes

$$R_{a.c.}/R_{d.c.} \simeq \pi a(f/\rho)^{\frac{1}{2}}, \quad (5)$$

$a$  being the radius. By (6) § 17.32 the a.c. resistance per unit length is

$$R_{a.c.} \simeq (\rho f)^{\frac{1}{2}}/a. \quad (6)$$

**17.34. Resistance of rectangular strip.** Referring to Fig. 39 B we suppose that  $a_1/b_1 \gg 1$  and assume that the strip may be replaced by an elliptical conductor of equal cross-sectional area with  $a/b = a_1/b_1$ . Then it follows that

$$b = 2b_1 \pi^{-\frac{1}{2}}. \quad (1)$$

Substituting this in (4) § 17.33 leads to the result that for a rectangular strip, at an adequately high frequency

$$R_{a.c.}/R_{d.c.} \simeq 4b_1(f/\pi\rho)^{\frac{1}{2}} \log_e(4a_1/b_1). \quad (2)$$

*Numerical example.* Let

$$\left. \begin{aligned} 2a_1 &= 2.5 \text{ cm.} \\ 2b_1 &= 0.2 \text{ cm.} \end{aligned} \right\} \quad 4a_1/b_1 = 50.$$

$$f = 40 \times 10^6 \text{ cycles per second.}$$

$$\rho = 1600 \text{ absolute units, for copper.}$$

Then

$$\begin{aligned} \log_e(4a_1/b_1) &= 2.3026 \log_{10} 50 \\ &\simeq 3.92. \end{aligned} \quad (3)$$

Hence by (2)

$$\begin{aligned} R_{a.c.}/R_{d.c.} &\simeq 2 \times 0.2 (40 \times 10^6 / \pi \times 1600)^{\frac{1}{2}} \times 3.92 \\ &\simeq 140, \end{aligned} \quad (4)$$

so

$$R_{a.c.} \simeq 140 R_{d.c.} \quad (5)$$

**17.40. Heat conduction in elliptical cylinder [135].** We treat the case where the cylinder is long enough in comparison with its major axis for end effect to be neglected. If  $\theta$  is temperature,  $\kappa$  diffusivity, and  $t$  time, the two-dimensional equation for heat transmission, expressed in rectangular coordinates, is

$$\frac{\partial^2 \theta}{\partial x^2} + \frac{\partial^2 \theta}{\partial y^2} - \frac{1}{\kappa} \frac{\partial \theta}{\partial t} = 0. \quad (1)$$

Let  $(\theta - \theta_0) = \theta_1 = f(x, y)e^{-\kappa\nu^2 t}$ , where  $f(x, y)$  is a function independent of  $t$ , and the purpose of  $\nu$  will appear later. Then

$$\frac{\partial \theta}{\partial t} = -\kappa\nu^2 \theta, \quad (2)$$

and on substituting into (1) we obtain

$$\frac{\partial^2 f}{\partial x^2} + \frac{\partial^2 f}{\partial y^2} + \nu^2 f = 0. \quad (3)$$

Transforming (3) to elliptical coordinates, by § 9.20 we get

$$\frac{\partial^2 f_1}{\partial \xi^2} + \frac{\partial^2 f_1}{\partial \eta^2} + 2k^2(\cosh 2\xi - \cos 2\eta)f_1 = 0, \quad (4)$$

where  $k^2 = q = \frac{1}{4}\nu^2 h^2$ , and  $f_1$  is a function of  $\xi, \eta$ .

**17.41. Particular form of solution of (4) § 17.40.** If  $\chi(\xi)$ ,  $\psi(\eta)$  are functions of  $\xi, \eta$  alone, respectively, the appropriate solution takes the form  $\chi(\xi)\psi(\eta)$ . Herein we consider a case where the temperature distribution is symmetrical about both axes of the ellipse. Thus  $\psi(\eta)$  must be even and periodic in  $\eta$ , with period  $\pi$ . The only solution of (4) § 17.40 having these properties involves  $\text{ce}_{2n}(\eta, q)$  as a factor. For reasons similar to those given in § 17.11, the other factor is  $\text{Ce}_{2n}(\xi, q)$ . Hence a formal solution of (1) § 17.40, expressed in elliptical coordinates is

$$\theta_1 = (\theta - \theta_0) = f_1(\xi, \eta)e^{-\kappa\nu^2 t} = \sum_{n=0}^{\infty} C_{2n} \text{Ce}_{2n}(\xi, q) \text{ce}_{2n}(\eta, q) e^{-\kappa\nu^2 t}. \quad (1)$$

**17.42. Boundary conditions.** We take the simple conditions that

- (a)  $\theta = 0, t < 0$ , throughout the cylinder;
- (b)  $\theta = \theta_0, t \geq 0$ , at the surface where  $\xi = \xi_0$ ;
- (c)  $\theta \rightarrow \theta_0, t \rightarrow +\infty, 0 \leq \xi \leq \xi_0$ .

The problem is to determine the temperature at any internal point

when  $t > 0$ . At the surface  $\xi = \xi_0$ , and when  $t \geq 0$ ,  $(\theta - \theta_0) = \theta_1 = 0$ , so by (1) § 17.41 we must have

$$C_{2n}(\xi_0, q) = 0. \quad (1)$$

Thus  $q$  has those values  $q_{2n,m}$  which make  $C_{2n}(\xi_0, q)$  vanish, i.e. the parametric zeros of the function. Now as  $t \rightarrow -0$ ,  $\theta = 0$ ,  $\theta_1 = -\theta_0$ , and (1) § 17.41 becomes

$$-\theta_0 = \sum_{n=0}^{\infty} \sum_{m=1}^{\infty} C_{2n} C_{2n}(\xi, q_{2n,m}) c_{2n}(\eta, q_{2n,m}), \quad (2)$$

so we have to determine the  $C_{2n}$ .

**17.43. Determination of  $C_{2n}$ .** We employ the orthogonality theorem in § 9.40. Accordingly we multiply each side of (2) § 17.42 by  $C_{2p}(\xi, q_{2p,r}) c_{2p}(\eta, q_{2p,r}) (\cosh 2\xi - \cos 2\eta)$  and integrate with respect to  $\eta$  from 0 to  $2\pi$ , and with respect to  $\xi$  from 0 to  $\xi_0$ . Then the r.h.s. vanishes except when  $p = n$ ,  $r = m$ , so

$$\begin{aligned} -\theta_0 \int_0^{\xi_0} \int_0^{2\pi} C_{2n}(\xi, q_{2n,m}) c_{2n}(\eta, q_{2n,m}) (\cosh 2\xi - \cos 2\eta) d\xi d\eta \\ = C_{2n} \int_0^{\xi_0} \int_0^{2\pi} C_{2n}^2(\xi, q_{2n,m}) c_{2n}^2(\eta, q_{2n,m}) (\cosh 2\xi - \cos 2\eta) d\xi d\eta. \end{aligned} \quad (1)$$

Taking individual integrals, we have (see (9) § 9.40 for  $\Theta_{2n}$ )

$$\begin{aligned} \int_0^{2\pi} c_{2n}(\eta, q_{2n,m}) \cos 2\eta d\eta &= \pi A_2^{(2n)}; & \int_0^{2\pi} c_{2n}^2(\eta, q_{2n,m}) d\eta &= \pi; \\ \int_0^{2\pi} c_{2n}(\eta, q_{2n,m}) d\eta &= 2\pi A_0^{(2n)}; & \int_0^{2\pi} c_{2n}^2(\eta, q_{2n,m}) \cos 2\eta d\eta &= \pi \Theta_{2n}. \end{aligned} \quad (2)$$

Hence (1) may be written

$$\begin{aligned} -\pi \theta_0 \int_0^{\xi_0} C_{2n}(\xi, q_{2n,m}) [2A_0^{(2n)} \cosh 2\xi - A_2^{(2n)}] d\xi \\ = \pi C_{2n} \int_0^{\xi_0} C_{2n}^2(\xi, q_{2n,m}) [\cosh 2\xi - \Theta_{2n}] d\xi, \end{aligned} \quad (3)$$

$$\text{so} \quad C_{2n} = \frac{-\theta_0 \int_0^{\xi_0} C_{2n}(\xi, q_{2n,m}) [2A_0^{(2n)} \cosh 2\xi - A_2^{(2n)}] d\xi}{\int_0^{\xi_0} C_{2n}^2(\xi, q_{2n,m}) [\cosh 2\xi - \Theta_{2n}] d\xi}. \quad (4)$$

The first integral in the numerator is evaluated in § 14.10; for that in the denominator see § 14.22.

Using (4) in (1) § 17.41 we obtain

$$\theta = \theta_0 \left\{ 1 - \sum_{n=0}^{\infty} \sum_{m=1}^{\infty} e^{-\kappa \nu_{2n,m}^2 t} \text{Ce}_{2n}(\xi, q_{2n,m}) \text{ce}_{2n}(\eta, q_{2n,m}) \times \right. \\ \left. \times \frac{\int_0^{\xi_0} \text{Ce}_{2n}(\xi, q_{2n,m}) [2A_0^{(2n)} \cosh 2\xi - A_2^{(2n)}] d\xi}{\int_0^{\xi_0} \text{Ce}_{2n}^2(\xi, q_{2n,m}) [\cosh 2\xi - \Theta_{2n}] d\xi} \right\}, \quad (5)$$

where  $\nu_{2n,m}^2 h^2 = 4q_{2n,m}$ . This gives the temperature at any point  $(\xi, \eta)$  of the cross-section when  $t \geq 0$ . Since the factor in (5) involving the integrals is independent of  $\xi, \eta$ , (5) is a solution of (1) § 17.40 expressed in elliptical coordinates. Also (1)  $\theta = \theta_0$  for  $t \geq 0$  at the surface where  $\xi = \xi_0$ , since  $\text{Ce}_{2n}(\xi_0, q_{2n,m}) = 0$ ; (2)  $\theta \rightarrow \theta_0$  everywhere when  $t \rightarrow +\infty$ , since  $e^{-\kappa \nu_{2n,m}^2 t} \rightarrow 0$ . Hence the boundary conditions (b), (c) § 17.42 are satisfied.

**17.44. Transition to circular cylinder.** We commence with (1) § 17.41 and by aid of Appendix I find that it degenerates to

$$\theta_1 = \sum_{n=0}^{\infty} C_{2n} p'_{2n} e^{-\kappa k_1^2 t} J_{2n}(k_1 r) \cos 2n\phi, \quad (1)$$

with  $k_1 = \nu_{2n,m}$ . Since  $\theta_1$  is now independent of  $\phi$ , by virtue of condition (b) § 17.42, all terms in (1) must vanish except  $n = 0$ .† Thus

$$\theta_1 = C_0 p'_0 J_0(k_1 r) e^{-\kappa k_1^2 t}. \quad (2)$$

At the surface  $r = a$ ,  $\theta = \theta_0$ , so  $k_1 a = \alpha_{0,m}$ ,  $m = 1, 2, 3, \dots$ , these being the roots of  $J_0(k_1 a) = 0$ . Also as  $e \rightarrow 0$ ,  $\xi \rightarrow +\infty$ ,  $\sinh \xi \rightarrow \cosh \xi$ ,  $r \rightarrow h \cosh \xi$  ( $h \rightarrow 0$ ),  $dr \rightarrow h \sinh \xi d\xi$  (see § 9.12),

$$\cosh 2\xi d\xi \rightarrow 2 \cosh \xi \sinh \xi d\xi \simeq 2r dr/h^2.$$

Using these and  $\text{Ce}_0(\xi, q_{0,m}) \rightarrow p'_0 J_0(\alpha_{0,m} r/a)$ ,  $\text{ce}_0(\eta, q_{0,m}) \rightarrow 2^{-1}$ ,  $A_0^{(0)} \rightarrow 2^{-1}$ ,  $A_2^{(0)} \rightarrow 0$ ,  $\Theta_{2n} \rightarrow 0$ ,  $\nu_{0,m}^2 \rightarrow \alpha_{0,m}^2/a^2$  (since by Appendix I,  $q \rightarrow 0$  as  $e \rightarrow 0$ ), (5) § 17.43 degenerates to

$$\theta = \theta_0 \left\{ 1 - \sum_{m=1}^{\infty} e^{-\kappa \alpha_{0,m}^2 t/a^2} J_0(\alpha_{0,m} r/a) \frac{\int_0^a r J_0(\alpha_{0,m} r/a) dr}{\int_0^a r J_0^2(\alpha_{0,m} r/a) dr} \right\}, \quad (3)$$

where  $\alpha_m$  has been written for  $\alpha_{0,m}$ .

$$\text{Now} \quad \int_0^a r J_0(\alpha_m r/a) dr = \frac{a^2}{\alpha_m} J_1(\alpha_m), \quad (4)$$

† A mathematical proof is given in [135].

and

$$\int_0^a r J_0^2(\alpha_m r/a) dr = \frac{1}{2} a^2 [J_1^2(\alpha_m) + J_0^2(\alpha_m)] = \frac{1}{2} a^2 J_1^2(\alpha_m), \quad (5)$$

since  $J_0(\alpha_m) = 0$ . Substituting from (4), (5) into (3) leads to the well-known result for a circular cylinder, namely,

$$\theta = \theta_0 \left[ 1 - 2 \sum_{m=1}^{\infty} \frac{J_0(\alpha_m r/a)}{\alpha_m J_1(\alpha_m)} e^{-\kappa \alpha_m^2 / a^2} \right]. \quad (6)$$

**17.50. An electromagnetic problem analogous to heat conduction [135].** The problems in § 17.10 and § 17.40 are analogous, provided the conditions are analogous. For the electromagnetic problem they are as follow:

- (a)  $H = 0$ ,  $t < 0$ , throughout the metal core;
- (b)  $H = H_0 = 4\pi n I_0 / l$ ,  $t \geq 0$ , at the surface where  $\xi = \xi_0$ ;
- (c)  $H \rightarrow H_0$ ,  $t \rightarrow +\infty$ ,  $0 \leq \xi \leq \xi_0$ .

Interpreted physically these conditions imply that at  $t = 0$  a battery is connected to the solenoid through a high resistance  $R$ , such that the time taken for the current to attain a substantially steady value  $I_0$  is small enough to be ignored. Thus for analytical purposes the current-time relationship is represented by Heaviside's unit function. The problem is to find  $H$  at any point of the cross-section of the metal core, and thence to calculate the inductance (variable) of the solenoid due to the core alone, when  $t > 0$ .

The differential equation for  $H$  is (1) § 17.10. If in (1) § 17.40 we write  $H$  for  $\theta$  and  $4\pi\mu/\rho$  for  $1/\kappa$ , the two equations are alike. Hence *mutatis mutandis*, (1) § 17.41 is a formal solution of (1) § 17.10, so we have

$$H - H_0 = \sum_{n=0}^{\infty} C_{2n} \text{Ce}_{2n}(\xi, q) \text{ce}_{2n}(\eta, q) e^{-\rho \nu^2 / 4\pi\mu}. \quad (1)$$

The solution which satisfies the above boundary conditions is (5) § 17.43, with  $H$  written for  $\theta$ . Thus we get

$$H = \frac{4\pi n I_0}{l} \left[ 1 - \sum_{n=0}^{\infty} \sum_{m=1}^{\infty} e^{-\rho \nu^2 n_m / 4\pi\mu} \text{Ce}_{2n}(\xi, q_{2n,m}) \text{ce}_{2n}(\eta, q_{2n,m}) \times \right. \\ \left. \times \frac{\int_0^{\xi_0} \text{Ce}_{2n}(\xi) [A_0^{(2n)} \cosh 2\xi - A_0^{(2n)}] d\xi}{\int_0^{\xi_0} \text{Ce}_{2n}^2(\xi) [\cosh 2\xi - \Theta_{2n}] d\xi} \right]. \quad (2)$$

When the ellipse tends to a circle, this expression degenerates to a known form for a metal core of circular cross-section [203; (4) p. 242].

**17.51. Inductance due to core alone.** This is defined to be the total flux interlinkage arising from the magnetization of the core, when unit current (unidirectional) flows in the  $n$  turn winding. If  $\Phi$  is the total core flux, then

$$L = \Phi n / I_0 = \frac{\mu n}{I_0} \iint H ds_1 ds_2, \quad (1)$$

where  $ds_1 ds_2$  is an elemental area of cross-section. Now by § 9.12

$$ds_1 = \frac{h}{2^{\frac{1}{2}}} (\cosh 2\xi - \cos 2\eta)^{\frac{1}{2}} d\xi \quad (2)$$

and 
$$ds_2 = \frac{h}{2^{\frac{1}{2}}} (\cosh 2\xi - \cos 2\eta)^{\frac{1}{2}} d\eta, \quad (3)$$

so 
$$L = \frac{h^2 \mu n}{2I_0} \int_0^{\xi_0} \int_0^{2\pi} H (\cosh 2\xi - \cos 2\eta) d\xi d\eta. \quad (4)$$

Substituting for  $H$  from (2) § 17.50 into (4) and using the analysis in § 17.43 leads to

$$L = \frac{4\pi^2 n^2 ab \mu}{l} \left[ 1 - \frac{h^2}{2ab} \sum_{n=0}^{\infty} \sum_{m=1}^{\infty} e^{-\rho v_{1n,m}^2 / 4\pi \mu} \times \frac{\left\{ \int_0^{\xi_0} \text{Ce}_{2n}(\xi, q_{2n,m}) [2A_0^{(2n)} \cosh 2\xi - A_2^{(2n)}] d\xi \right\}^2}{\int_0^{\xi_0} \text{Ce}_{2n}^2(\xi, q_{2n,m}) [\cosh 2\xi - \Theta_{2n}] d\xi} \right]. \quad (5)$$

For evaluation of some of the integrals, see §§ 14.10, 14.22.

When the ellipse tends to a circle, (5) degenerates to a known form [203; (14) p. 240].

## XVIII

### ELECTROMAGNETIC WAVE GUIDES

**18.10. Introduction.** From 1888, when electromagnetic waves were first demonstrated, till about 1936, attention was concentrated chiefly on their propagation in the atmosphere surrounding the earth. It is possible, however, to confine electromagnetic waves to the air space *within* a metal tube. Propagation of this nature was treated experimentally and theoretically more than half a century ago. The subject has been retrieved from the academical archives, owing to developments in ultra high-frequency technique. There are now ultra high-frequency electronic devices for generating frequencies exceeding  $3 \times 10^9$  cycles per second, i.e. wave-lengths less than 10 cm. Analysis has revealed that if the electromagnetic power is transmitted to an aerial by a *transmission line*, e.g. a parallel wire or a coaxial cylinder system, the loss† exceeds appreciably that incurred when the power is transmitted as *electromagnetic waves through the air in a uniform highly conducting tube*. Since the power is confined within the tube, it is guided, so the tube is called a wave guide. The subject has now attained considerable importance, and deserves detailed treatment here. Moreover, we shall not confine our analysis to the case where Mathieu functions are involved, but lead up to it from two simpler cases, thereby introducing a difficult subject gradually. References to numerous papers dealing with wave guides will be found in [199].

**18.11. Rectangular wave guide.** Analytically this is the simplest case. The convention adopted for cartesian coordinates is illustrated in Fig. 40, the  $z$ -axis being parallel to the axis of the guide and constituting the inner left lower corner. At the near end, containing the origin  $O$ , we suppose that there is a device for exciting electromagnetic waves, which are propagated parallel to the  $z$ -axis, in the direction of the arrow. We assume that the guide is so long that the influence of reflection from the far end at an intermediate point may be disregarded. Alternatively we may consider the guide to be relatively short, but terminated at its far end by an appropriate

† Expressed as a percentage of the input power at the transmitting end of the line.

impedance, such that reflection is negligible, as is the case in practice. Moreover, the transmission is unidirectional.

Power is transmitted down the guide in one or more of the 'modes' to which the system responds.† To investigate these we have to solve Maxwell's equations for the electromagnetic field, subject to the particular condition which obtains at the inner surface of the guide. Unless we postulate absence of loss due to eddy currents in

FIG. 40. Coordinate system in rectangular wave guide.

the wall of the guide, it is difficult to formulate a precise boundary condition.‡ Assuming zero resistivity for the metal of the guide, the condition is that the tangential component of the electric field in the air must vanish at the inner surface.

**18.20. Maxwell's equations.** For an isotropic non-conducting dielectric of permeability  $\mu$  and dielectric constant  $\epsilon$ , the 'curl' equations in vector form (heavy type) are

$$\epsilon \frac{\partial \mathbf{E}}{\partial t} = \text{curl } \mathbf{H}, \quad (1)$$

$$\mu \frac{\partial \mathbf{H}}{\partial t} = -\text{curl } \mathbf{E}, \quad (2)$$

where  $\mathbf{E}$  designates an electric, and  $\mathbf{H}$  a magnetic force space vector.

The vectors  $\mathbf{E}$  and  $\mathbf{H}$  can each be resolved into components parallel to the axes  $X, Y, Z$  of Fig. 40. Let the scalar components be denoted

† For power to be propagated down the guide, it may be shown by § 18.24 that the width must be  $> \frac{1}{2}\lambda$ , where  $\lambda$  is the wavelength in an *unbounded* dielectric.

‡ Loss in the dielectric (air) is also assumed to be zero, i.e. it is a perfect insulator.

by  $E_x$ ,  $E_y$ ,  $E_z$ , and  $H_x$ ,  $H_y$ ,  $H_z$ , respectively. Then in terms of cartesian coordinates, (1) yields the equations:

$$\epsilon \frac{\partial E_x}{\partial t} = -\frac{\partial H_y}{\partial z} + \frac{\partial H_z}{\partial y}, \quad (3)$$

$$\epsilon \frac{\partial E_y}{\partial t} = -\frac{\partial H_z}{\partial x} + \frac{\partial H_x}{\partial z}, \quad (4)$$

$$\epsilon \frac{\partial E_z}{\partial t} = -\frac{\partial H_x}{\partial y} + \frac{\partial H_y}{\partial x}. \quad (5)$$

To aid memorization it should be observed that in (1), (2)  $\mathbf{E}$  and  $\mathbf{H}$  are interchanged,  $\epsilon$  is on the l.h.s. with  $\mathbf{E}$ , and  $\mu$  on the l.h.s. with  $\mathbf{H}$ , but with a negative curl. Equations (3)–(5) come from (1), and their subscripts are in cyclic order. The subscripts and coordinates (in denominators) in the last two members of each equation are interchanged. Thus by memorizing (1)–(3) all formulae of the set (3)–(8) may be written down.

For the components of magnetic force we have from (2)—using (3) as a pattern—

$$\mu \frac{\partial H_x}{\partial t} = \frac{\partial E_y}{\partial z} - \frac{\partial E_z}{\partial y}, \quad (6)$$

$$\mu \frac{\partial H_y}{\partial t} = \frac{\partial E_z}{\partial x} - \frac{\partial E_x}{\partial z}, \quad (7)$$

$$\mu \frac{\partial H_z}{\partial t} = \frac{\partial E_x}{\partial y} - \frac{\partial E_y}{\partial x}. \quad (8)$$

**18.21. Cosinusoidal variation of  $\mathbf{E}$  and  $\mathbf{H}$ .** It is expedient to make this choice so that various transmission modes may be segregated. At any section distant  $z$  from  $O$  in Fig. 40 the electric and magnetic force vectors are in phase and vary in accordance with the real part of  $e^{i\omega t}$ . If the phase at any  $z$  is referred to  $O$ , account must be taken of the velocity of *phase* propagation down the guide. The instantaneous distribution of  $\mathbf{E}$  and  $\mathbf{H}$  along the guide depends upon the real part of  $e^{i\omega t}e^{-i\beta z}$ , i.e.  $\cos(\omega t - \beta z)$ , where  $\beta$  is a coefficient such that  $\beta z$  defines the phase at  $z$  with respect to its value at  $O$ . For transmission of power down the guide, it can be shown that  $\beta$  must be real [see 210].

**18.22. Simplification of equations in § 18.20.** This is effected by writing  $i\omega$  for  $\partial/\partial t$ , and  $-i\beta$  for  $\partial/\partial z$ , in accordance with § 18.21. Then (3)–(8) § 18.20 become

$$i\omega\epsilon E_x = i\beta H_y + \frac{\partial H_z}{\partial y}, \quad (1)$$

$$i\omega\epsilon E_y = -\frac{\partial H_z}{\partial x} - i\beta H_x, \quad (2)$$

$$i\omega\epsilon E_z = -\frac{\partial H_x}{\partial y} + \frac{\partial H_y}{\partial x}, \quad (3)$$

$$i\omega\mu H_x = -i\beta E_y - \frac{\partial E_z}{\partial y}, \quad (4)$$

$$i\omega\mu H_y = \frac{\partial E_z}{\partial x} + i\beta E_x, \quad (5)$$

$$i\omega\mu H_z = \frac{\partial E_x}{\partial y} - \frac{\partial E_y}{\partial x}. \quad (6)$$

Substituting for  $iE_y$  from (2) into (4), and for  $iE_x$  from (1) into (5), gives

$$k_1^2 H_x = -i\beta \frac{\partial H_z}{\partial x} + i\omega\epsilon \frac{\partial E_z}{\partial y} \quad (7)$$

and 
$$k_1^2 H_y = -i\beta \frac{\partial H_z}{\partial y} - i\omega\epsilon \frac{\partial E_z}{\partial x}, \quad (8)$$

where  $k_1^2 = \mu\epsilon\omega^2 - \beta^2 = (\omega/c)^2 - \beta^2$  and  $c = 1/(\mu\epsilon)^{\frac{1}{2}}$ , the velocity of light. Substituting for  $iH_y$  from (5) into (1), and for  $iH_x$  from (4) into (2), gives

$$k_1^2 E_x = -i\beta \frac{\partial E_z}{\partial x} - i\omega\mu \frac{\partial H_z}{\partial y} \quad (9)$$

and 
$$k_1^2 E_y = -i\beta \frac{\partial E_z}{\partial y} + i\omega\mu \frac{\partial H_z}{\partial x}. \quad (10)$$

Using (7), (8) in (3) for  $H_x$ ,  $H_y$  leads to the two-dimensional wave equation

$$\frac{\partial^2 E_z}{\partial x^2} + \frac{\partial^2 E_z}{\partial y^2} + k_1^2 E_z = 0. \quad (11)$$

Similarly from (9), (10), and (6), we obtain

$$\frac{\partial^2 H_z}{\partial x^2} + \frac{\partial^2 H_z}{\partial y^2} + k_1^2 H_z = 0. \quad (12)$$

**18.23. Solution of (11) § 18.22.** Write  $E_z = \psi(x)\xi(y)$ , where  $\psi$  is a function of  $x$  alone, and  $\xi$  is a function of  $y$  alone. Then

$$\xi \frac{d^2\psi}{dx^2} + \psi \frac{d^2\xi}{dy^2} = -k_1^2 \psi \xi, \quad (1)$$

where  $k_1^2 = (\omega/c)^2 - \beta^2$ . Dividing throughout by  $\psi\xi$ , (1) becomes

$$\frac{1}{\psi} \frac{d^2\psi}{dx^2} + k_1^2 = -\frac{1}{\xi} \frac{d^2\xi}{dy^2}. \quad (2)$$

Introducing a separation constant  $l^2$ , as in § 9.21, we obtain two ordinary differential equations, namely,

$$\frac{d^2\psi}{dx^2} + (k_1^2 - l^2)\psi = 0 \quad (3)$$

and

$$\frac{d^2\xi}{dy^2} + l^2\xi = 0. \quad (4)$$

The formal solutions of (3), (4) are: (a)  $\cos[x(k_1^2 - l^2)^{\frac{1}{2}}]$ ,  $\sin[x(k_1^2 - l^2)^{\frac{1}{2}}]$ ; (b)  $\cos ly$ ,  $\sin ly$ , respectively. From these we have to construct a solution which satisfies the boundary condition  $E_z = 0$ , at the inner plane faces of the guide, i.e. at  $x = 0, a$ ;  $y = 0, b$ . Since  $\cos(0) = 1$ , the cosine solutions are inadmissible, so we take

$$E_z = \psi\xi = A \sin[x(k_1^2 - l^2)^{\frac{1}{2}}] \sin ly, \quad (5)$$

$A$  being an arbitrary constant. Now  $E_z$  vanishes when  $x = 0$  or  $y = 0$ . For it to vanish at  $x = a$ ,  $y = b$ , we must have, respectively,  $a(k_1^2 - l^2)^{\frac{1}{2}} = m\pi$ ,  $bl = n\pi$ ,  $m$  and  $n$  being any positive integers. Then eliminating  $l$  by squaring and adding, we get

$$k_1^2 = \pi^2 \left[ \left( \frac{m}{a} \right)^2 + \left( \frac{n}{b} \right)^2 \right]. \quad (6)$$

Selecting the real part of the phase factor  $e^{i(\omega t - \beta z)}$ , an appropriate solution of (11) § 18.22 is

$$E_z = A \sin \frac{\pi m x}{a} \sin \frac{\pi n y}{b} \cos(\omega t - \beta z). \quad (7)$$

This defines a wave system in the rectangular guide. By assigning integral values to  $m$ ,  $n$  the modes of transmission may be specified. There is, however, a limitation associated with  $\beta$ , which we shall now investigate.

**18.24. Cut-off or critical pulsance.** Since  $\beta^2 = (\omega/c)^2 - k_1^2$ , from (6) § 18.23 we get

$$\beta^2 = (\omega/c)^2 - \pi^2 \left[ (m/a)^2 + (n/b)^2 \right]. \quad (1)$$

For power to be transmitted down the guide,  $\beta$  must be real [210], so it follows that

$$\omega > \pi c[(m/a)^2 + (n/b)^2]^{\frac{1}{2}}. \quad (2)$$

Hence, if  $m, n$  be assigned, there is a pulsance

$$\omega_c = \pi c[(m/a)^2 + (n/b)^2]^{\frac{1}{2}}, \quad (3)$$

below which transmission of power ceases. This is termed the cut-off or critical pulsance, and it corresponds to  $\beta = 0$ . Its value depends for a given guide upon  $m, n$ . If  $\omega$  is fixed but exceeds  $\omega_c$ , there is only a finite number of  $m, n$  combinations (modes of transmission) for which the inequality can be satisfied.

**18.25.  $E$  or transverse magnetic wave.** (11), (12) § 18.22 are two linearly independent equations, so the solution of (11) holds if that of (12) is  $H_z = 0$ , which implies  $\partial H_z / \partial x \equiv 0 \equiv \partial H_z / \partial y$ . Then from (9), (10) § 18.22

$$E_x = -\frac{i\beta}{k_1^2} \frac{\partial E_z}{\partial x}; \quad \text{and} \quad E_y = -\frac{i\beta}{k_1^2} \frac{\partial E_z}{\partial y}. \quad (1)$$

Applying these to (7) § 18.23 yields, using  $e^{i(\omega t - \beta z)}$  for  $\cos(\omega t - \beta z)$ ,  $-i = e^{-\frac{1}{2}\pi i}$ , and taking the real part,

$$\begin{aligned} E_x &= A \frac{\beta}{k_1^2} \frac{\pi m}{a} \cos \frac{\pi m x}{a} \sin \frac{\pi n y}{b} \sin(\omega t - \beta z); \\ E_y &= A \frac{\beta}{k_1^2} \frac{\pi n}{b} \sin \frac{\pi m x}{a} \cos \frac{\pi n y}{b} \sin(\omega t - \beta z). \end{aligned} \quad (2)$$

Also from (1), (2) § 18.22

$$H_x = -(\omega \epsilon / \beta) E_y; \quad H_y = (\omega \epsilon / \beta) E_x. \quad (3)$$

Collecting the six results, we have

$$E_x = A(\beta/k_1^2)(\pi m/a) \cos(\pi m x/a) \sin(\pi n y/b) \sin(\omega t - \beta z), \quad (4)$$

$$E_y = A(\beta/k_1^2)(\pi n/b) \sin(\pi m x/a) \cos(\pi n y/b) \sin(\omega t - \beta z), \quad (5)$$

$$E_z = A \sin(\pi m x/a) \sin(\pi n y/b) \cos(\omega t - \beta z); \quad (6)$$

$$H_x = -A(\omega \epsilon / k_1^2)(\pi n/b) \sin(\pi m x/a) \cos(\pi n y/b) \sin(\omega t - \beta z), \quad (7)$$

$$H_y = A(\omega \epsilon / k_1^2)(\pi m/a) \cos(\pi m x/a) \sin(\pi n y/b) \sin(\omega t - \beta z), \quad (8)$$

$$H_z \equiv 0. \quad (9)$$

In the type of wave to which these results refer, the electric force at any non-boundary point has components in the  $x, y, z$  directions. The magnetic force, however, has components in the  $x, y$  directions only, so it is wholly transverse to the direction of propagation. For this reason the wave is called an  $E$  or *transverse magnetic type*. It may conveniently be denoted by the symbol  $E_{m,n}$ ,  $m, n$  indicating

the particular mode of transmission. When  $m = 0$  for any  $n$ , or vice versa, (4)–(8) vanish. Hence transverse magnetic waves of the types  $E_{0,n}$ ,  $E_{m,0}$  do not exist. The lowest mode possible is with  $m = n = 1$ , i.e.  $E_{1,1}$ , which has the lowest cut-off frequency.

**18.26.  $H$  or transverse electric wave.** The linear independence of (11), (12) § 18.22 permits us to take  $E_z \equiv 0$ , which implies  $\partial E_z / \partial x \equiv 0 \equiv \partial E_z / \partial y$ . Then from (9), (10) § 18.22

$$\frac{\partial H_z}{\partial y} = \frac{ik_1^2}{\omega\mu} E_x; \quad \frac{\partial H_z}{\partial x} = -\frac{ik_1^2}{\omega\mu} E_y. \quad (1)$$

Since  $E_x = 0$  at  $y = 0, b$ , whilst  $E_y = 0$  at  $x = 0, a$ , it follows from (1) that the appropriate conditions to be satisfied by  $H_z$  are

$$\partial H_z / \partial y = 0 \quad \text{at } y = 0, b; \quad \partial H_z / \partial x = 0 \quad \text{at } x = 0, a. \quad (2)$$

Referring back to § 18.23 we now use the cosine solutions of (12) § 18.22 and obtain, with an arbitrary constant  $B$ ,

$$H_z = B \cos \frac{\pi m x}{a} \cos \frac{\pi n y}{b} \cos(\omega t - \beta z), \quad (3)$$

which satisfies the conditions (2).

Then from (7), (8) § 18.22

$$H_x = -\frac{i\beta}{k_1^2} \frac{\partial H_z}{\partial x}; \quad H_y = -\frac{i\beta}{k_1^2} \frac{\partial H_z}{\partial y}, \quad (4)$$

while from (4), (5) § 18.22

$$E_x = \frac{\omega\mu}{\beta} H_y; \quad E_y = -\frac{\mu\omega}{\beta} H_x. \quad (5)$$

Applying (4), (5) to (3), we obtain

$$E_x = -B \frac{\omega\mu}{k_1^2} \frac{\pi n}{b} \cos \frac{\pi m x}{a} \sin \frac{\pi n y}{b} \sin(\omega t - \beta z), \quad (6)$$

$$E_y = B \frac{\mu\omega}{k_1^2} \frac{\pi m}{a} \sin \frac{\pi m x}{a} \cos \frac{\pi n y}{b} \sin(\omega t - \beta z), \quad (7)$$

$$E_z \equiv 0; \quad (8)$$

$$H_x = -B \frac{\beta}{k_1^2} \frac{\pi m}{a} \sin \frac{\pi m x}{a} \cos \frac{\pi n y}{b} \sin(\omega t - \beta z), \quad (9)$$

$$H_y = -B \frac{\beta}{k_1^2} \frac{\pi n}{b} \cos \frac{\pi m x}{a} \sin \frac{\pi n y}{b} \sin(\omega t - \beta z), \quad (10)$$

$$H_z = B \cos \frac{\pi m x}{a} \cos \frac{\pi n y}{b} \cos(\omega t - \beta z). \quad (11)$$

In the type of wave to which these results pertain, the magnetic force at any non-boundary point has components in the  $x$ ,  $y$ ,  $z$

directions. The electric force, however, has components in the  $x, y$  directions only, so it is wholly transverse to the direction of propagation. For this reason the wave is called an  $H$  or *transverse electric*

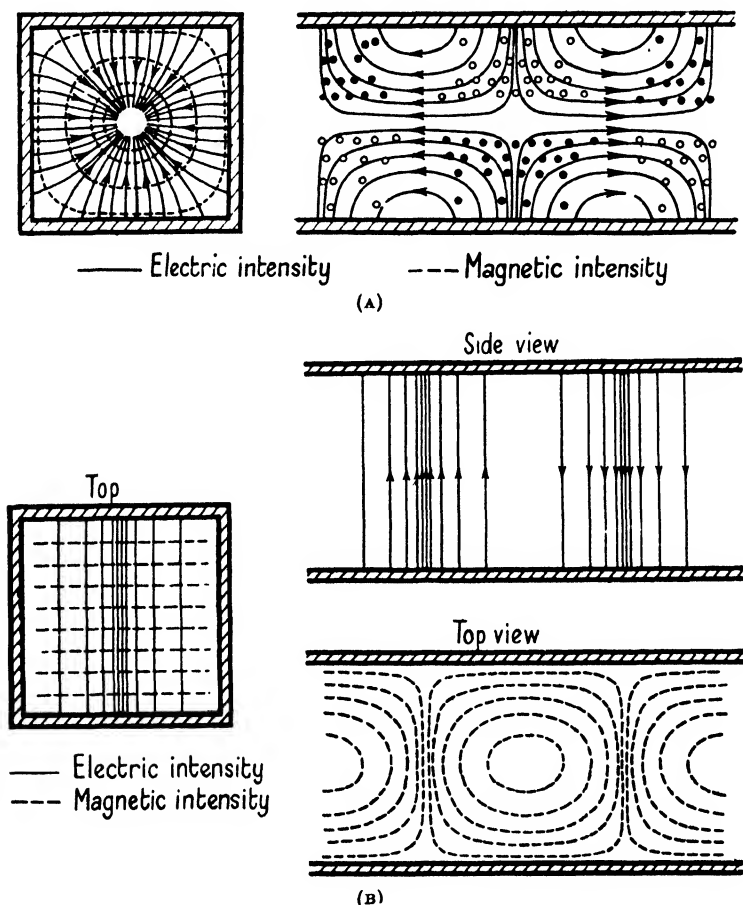

FIG. 41. Lines of electric (—) and magnetic force (---) in rectangular wave guide: (A)  $E_{1,1}$  wave; (B)  $H_{1,0}$  wave.

*type*. It may conveniently be denoted by the symbol  $H_{m,n}$ ,  $m, n$  indicating the particular mode of transmission. When  $m = n = 0$ , all components in (6)–(11) vanish except  $H_z$ . Since the electric and magnetic components cannot exist independently, there is no wave of type  $H_{0,0}$ . But if  $m = 0, n = 1$ , or  $m = 1, n = 0$ , the waves exist. If  $b > a$ , the  $H_{0,1}$  wave has the lowest cut-off frequency, but if  $b < a$ ,  $H_{1,0}$  possesses this attribute, as will be evident from (3) § 18.24.

The lines of electric and magnetic force in a rectangular wave guide are illustrated in Fig. 41.

**18.30. Orthogonal curvilinear coordinates.** In solving Maxwell's equations for the electromagnetic field, the equations for the components of electric and magnetic force must be expressed in terms of the appropriate coordinates. For a rectangular wave guide, the equations may be written down immediately in cartesian coordinates. When the guide has a curved cross-section it is expedient

FIG. 42. Orthogonal curvilinear coordinates.

to employ orthogonal curvilinear coordinates. These are determined by the common point of three surfaces which intersect mutually at right angles. This may be illustrated by aid of Fig. 42 which refers to the cylindrical polar coordinates  $r, \theta, z$ . The point  $P$  is the common intersection of (1) the curved surface of the cylinder of radius  $r$ , (2) a plane through  $P$  perpendicular to the axis  $Oz$ , (3) a plane containing  $Oz$  and passing through  $P$ . These three surfaces intersect orthogonally. Then from Fig. 42A,B we see that  $x = r \cos \theta$ ,  $y = r \sin \theta$ ,  $z = z$  itself. The lengths of the edges of the elemental solid in Fig. 42B are, respectively,  $dr$ ,  $r d\theta$ , and  $dz$ . The first and third are straight, but the second is curved.

Now consider the coordinates from a general viewpoint (each of the three curves at the intersection having finite curvature), and let them be  $\varphi_1, \varphi_2, \varphi_3$ , respectively. The lengths of the edges of the solid are  $ds_1 = l_1 d\varphi_1$ ,  $ds_2 = l_2 d\varphi_2$ ,  $ds_3 = l_3 d\varphi_3$ , where  $l_1, l_2, l_3$  are multiplying factors depending upon the particular system of coordinates. In general they will vary with the position of  $P$  in space. For

cylindrical polars  $\varphi_1 = r$ ,  $\varphi_2 = \theta$ ,  $\varphi_3 = z$ ,  $ds_1 = dr$ ,  $ds_2 = r d\theta$ ,  $ds_3 = dz$ ; so  $l_1 = 1$ ,  $l_2 = r$ , and  $l_3 = 1$ . For elliptical coordinates, Fig. 16,  $\varphi_1 = \xi$ ,  $\varphi_2 = \eta$ ,  $\varphi_3 = z$ ; so by (4) § 9.12,  $l_1 = l_2 = h[(\cosh 2\xi - \cos 2\eta)/2]^{\frac{1}{2}}$ , and since  $z = z$ ,  $l_3 = 1$ .

**18.31. Vector differential formulae.** We now introduce general formulae by means of which the scalar components  $A_1$ ,  $A_2$ ,  $A_3$  of a vector quantity  $\mathbf{A}$  may be expressed in terms of orthogonal curvilinear coordinates:

$$(\text{curl } \mathbf{A})_1 = \frac{1}{l_2 l_3} \left[ -\frac{\partial(l_2 A_2)}{\partial \varphi_3} + \frac{\partial(l_3 A_3)}{\partial \varphi_2} \right], \quad (1)$$

$$(\text{curl } \mathbf{A})_2 = \frac{1}{l_3 l_1} \left[ -\frac{\partial(l_3 A_3)}{\partial \varphi_1} + \frac{\partial(l_1 A_1)}{\partial \varphi_3} \right], \quad (2)$$

and 
$$(\text{curl } \mathbf{A})_3 = \frac{1}{l_1 l_2} \left[ -\frac{\partial(l_1 A_1)}{\partial \varphi_2} + \frac{\partial(l_2 A_2)}{\partial \varphi_1} \right]. \quad (3)$$

As an aid to memorization, note that, (a) the  $A$  occur in cyclic order, (b) the subscript on the l.h.s. does not occur on the r.h.s., (c) the subscripts on the r.h.s. are interchanged in denominator and numerator of the two differentials.

In the wave guides treated herein  $l_3 = 1$ ,  $\partial/\partial \varphi_3 = \partial/\partial z$  may be replaced (as in § 18.22) by  $-i\beta$ , whilst  $A_3 = A_z$ . Thus (1)–(3) become

$$(\text{curl } \mathbf{A})_1 = i\beta A_z + \frac{1}{l_2} \frac{\partial A_z}{\partial \varphi_2}, \quad (4)$$

$$(\text{curl } \mathbf{A})_2 = -\frac{1}{l_1} \frac{\partial A_z}{\partial \varphi_1} - i\beta A_1, \quad (5)$$

and 
$$(\text{curl } \mathbf{A})_z = \frac{1}{l_1 l_2} \left\{ -\frac{\partial(l_1 A_1)}{\partial \varphi_2} + \frac{\partial(l_2 A_2)}{\partial \varphi_1} \right\}. \quad (6)$$

These three formulae enable us to write down the components of the electric and magnetic fields for *any* type of uniform cylindrical wave guide.

**18.32. Form of general differential equation.** From (1), (2) § 18.20 and (4), (5), (6) § 18.31 we obtain

$$i\omega\epsilon E_1 = i\beta H_z + \frac{1}{l_2} \frac{\partial H_z}{\partial \varphi_2}, \quad (1)$$

$$i\omega\epsilon E_2 = -\frac{1}{l_1} \frac{\partial H_z}{\partial \varphi_1} - i\beta H_1, \quad (2)$$

$$i\omega\epsilon E_z = \frac{1}{l_1 l_2} \left\{ -\frac{\partial(l_1 H_1)}{\partial\varphi_2} + \frac{\partial(l_2 H_2)}{\partial\varphi_1} \right\}; \quad (3)$$

$$i\mu\omega H_1 = -i\beta E_2 - \frac{1}{l_2} \frac{\partial E_z}{\partial\varphi_2}, \quad (4)$$

$$i\mu\omega H_2 = \frac{1}{l_1} \frac{\partial E_z}{\partial\varphi_1} + i\beta E_1, \quad (5)$$

$$i\mu\omega H_z = \frac{1}{l_1 l_2} \left\{ \frac{\partial(l_1 E_1)}{\partial\varphi_2} - \frac{\partial(l_2 E_2)}{\partial\varphi_1} \right\}. \quad (6)$$

Substituting from (4) into (2) for  $iE_2$  gives

$$k_1^2 H_1 = i \left\{ \frac{\omega\epsilon}{l_2} \frac{\partial E_z}{\partial\varphi_2} - \frac{\beta}{l_1} \frac{\partial H_z}{\partial\varphi_1} \right\}, \quad (7)$$

with  $k_1^2 = (\omega/c)^2 - \beta^2$ .

Substituting from (5) into (1) for  $iE_1$  gives

$$k_1^2 H_2 = -i \left\{ \frac{\omega\epsilon}{l_1} \frac{\partial E_z}{\partial\varphi_1} + \frac{\beta}{l_2} \frac{\partial H_z}{\partial\varphi_2} \right\}. \quad (8)$$

Using the values of  $H_1$ ,  $H_2$  from (7), (8) in (3) leads to the general differential equation

$$\frac{1}{l_1^2} \frac{\partial^2 E_z}{\partial\varphi_1^2} + \frac{1}{l_2^2} \frac{\partial^2 E_z}{\partial\varphi_2^2} + \frac{1}{l_1 l_2} \left\{ \frac{\partial(l_2/l_1)}{\partial\varphi_1} \frac{\partial E_z}{\partial\varphi_1} + \frac{\partial(l_1/l_2)}{\partial\varphi_2} \frac{\partial E_z}{\partial\varphi_2} \right\} + k_1^2 E_z = 0. \quad (9)$$

In like manner an identical equation can be deduced for  $H_z$ .

**18.33. General formulae for  $E$  waves.** In accordance with § 18.25 we put  $H_z \equiv 0$ . Then from (1), (2) § 18.32 we get

$$E_1 = \frac{\beta}{\omega\epsilon} H_2 \quad (1)$$

$$\text{and} \quad E_2 = -\frac{\beta}{\omega\epsilon} H_1. \quad (2)$$

$$\text{By (7), (8) § 18.32} \quad H_1 = \frac{i\omega\epsilon}{k_1^2 l_2} \frac{\partial E_z}{\partial\varphi_2} \quad (3)$$

$$\text{and} \quad H_2 = -\frac{i\omega\epsilon}{k_1^2 l_1} \frac{\partial E_z}{\partial\varphi_1}. \quad (4)$$

From (1), (4) and (2), (3) we have

$$E_1 = -\frac{i\beta}{k_1^2 l_1} \frac{\partial E_z}{\partial\varphi_1} \quad (5)$$

$$\text{and} \quad E_2 = -\frac{i\beta}{k_1^2 l_2} \frac{\partial E_z}{\partial\varphi_2}. \quad (6)$$

Hence if  $E_z$  is determined from (9) § 18.32, the remaining components follow immediately from (3)–(6).

**18.34. General formulae for  $H$  waves.** In accordance with § 18.26 we put  $E_z \equiv 0$ . Then from (5), (4) § 18.32

$$E_1 = \frac{\mu\omega H_2}{\beta} \quad (1)$$

and 
$$E_2 = -\frac{\mu\omega H_1}{\beta}. \quad (2)$$

By (7), (8) § 18.32 
$$H_1 = -\frac{i\beta}{k_1^2 l_1} \frac{\partial H_z}{\partial \varphi_1} \quad (3)$$

and 
$$H_2 = -\frac{i\beta}{k_1^2 l_2} \frac{\partial H_z}{\partial \varphi_2}. \quad (4)$$

From (1), (4) and (2), (3)

$$E_1 = -\frac{i\mu\omega}{k_1^2 l_2} \frac{\partial H_z}{\partial \varphi_2} \quad (5)$$

and 
$$E_2 = \frac{i\mu\omega}{k_1^2 l_1} \frac{\partial H_z}{\partial \varphi_1}. \quad (6)$$

Hence, if  $H_z$  is determined from (9) § 18.32, the remaining components follow immediately from (3)–(6).

Having derived general formulae from  $E$  and  $H$  waves, we are now in a position to obtain the scalar components of the electric and magnetic forces in any uniform cylindrical wave guide whose cross-section is expressible in terms of two orthogonal curvilinear coordinates.

**18.40. Application of formulae in preceding sections to circular wave guide.** Referring to § 18.30 we have  $\varphi_1 = r$ ,  $\varphi_2 = \theta$ ,  $l_1 = 1$ ,  $l_2 = r$ , so  $\partial(l_1/l_2)/\partial\varphi_2 = \partial(1/r)/\partial\theta = 0$ , and (9) § 18.32 becomes

$$\frac{\partial^2 E_z}{\partial r^2} + \frac{1}{r} \frac{\partial E_z}{\partial r} + \frac{1}{r^2} \frac{\partial^2 E_z}{\partial \theta^2} + k_1^2 E_z = 0. \quad (1)$$

Assume that  $E_z = \zeta(r)\chi(\theta)$ , where  $\zeta$  is a function of  $r$  alone, and  $\chi$  one of  $\theta$  alone. Proceeding as in § 9.21 we get

$$\frac{r^2}{\zeta} \frac{d^2 \zeta}{dr^2} + \frac{r}{\zeta} \frac{d\zeta}{dr} + r^2 k_1^2 = -\frac{1}{\chi} \frac{d^2 \chi}{d\theta^2} = m^2, \quad \text{say,} \quad (2)$$

$m^2$  being the separation constant. Then the equation for  $\zeta$  is

$$\frac{d^2 \zeta}{dr^2} + \frac{1}{r} \frac{d\zeta}{dr} + \left(k_1^2 - \frac{m^2}{r^2}\right) \zeta = 0, \quad (3)$$

which is the standard differential equation for the Bessel functions of the two kinds of order  $m$ , namely,  $J_m(k_1 r)$ ,  $Y_m(k_1 r)$ . Now  $E_z$  must be finite on the axis of the guide, but  $Y_m(0) = -\infty$ , so the  $Y$  solution is inadmissible, and we retain only  $J_m(k_1 r)$ .

The equation for  $\chi$  is

$$\frac{d^2 \chi}{d\theta^2} + m^2 \chi = 0, \quad (4)$$

whose formal solutions  $\cos m\theta$ ,  $\sin m\theta$  are appropriate here. Accordingly as a composite solution of (1), with two arbitrary constants, we take

$$\zeta_m \chi_m = J_m(k_1 r) [\bar{A}_m \cos m\theta + \bar{B}_m \sin m\theta] = A_m J_m(k_1 r) \cos(m\theta - \alpha_m), \quad (5)$$

where  $A_m = (\bar{A}_m^2 + \bar{B}_m^2)^{1/2}$ ,  $\alpha_m = \tan^{-1}(\bar{B}_m/\bar{A}_m)$ . By suitable choice of datum line for  $\theta$  we can, without loss of generality, write  $m\theta$  for  $(m\theta - \alpha_m)$ . Then a formal solution of (1) is

$$E_{z_m} = A_m J_m(k_1 r) \cos m\theta \cos(\omega t - \beta z). \quad (6)$$

Now  $E_{z_m}$  is single-valued and periodic in the coordinate  $\theta$ , so we must have  $\cos m\theta = \cos m(\theta + 2\pi)$ . Hence  $m$  must be an integer, and since  $J_m = (-1)^m J_{-m}$ , we need consider positive integers only. Then (6) is a solution of (1) for  $m \geq 0$ , so a complete formal solution for the problem under consideration is

$$E_z = \sum_{m=0}^{\infty} A_m J_m(k_1 r) \cos(m\theta - \alpha_m), \quad (7)$$

the time factor being omitted.

The boundary condition is  $E_z = 0$  when  $r = a$  at the inner surface of the guide. Hence  $J_m(k_1 a) = 0$ , so that  $k_1 a$  must be a positive real zero of the B.F. of order  $m$ . For each  $m$  the B.F. has an infinite number of zeros, i.e. writing  $k_{m,r}$  for  $k_1$ ,  $J_m(k_{m,r} a) = 0$  for  $r = 1, 2, 3, \dots$ . Also there are an infinite number of B.F. corresponding to  $m = 0, 1, 2, \dots$ . Hence a double infinity of zeros is obtained. For power to be transmitted down the guide, by [210]  $\beta$  must be real. But  $\beta^2 = (\omega/c)^2 - k_{m,r}^2$ , so for the reality of  $\beta$  we must have  $\omega/c > k_{m,r}$ . Hence for each  $m$ , power is transmitted only in those modes, finite in number, for which  $\omega$  satisfies this inequality.

If  $m = 0$ , the first zero [202, p. 9] occurs when  $k_{0,1} a = 2.405$ , so  $k_{0,1} = 2.405a^{-1}$ . Then for an  $E_{0,1}$  wave

$$E_{z_{0,1}} = A_0 J_0(k_{0,1} r) \cos(\omega t - \beta z). \quad (8)$$

Now  $\beta^2 = (\omega/c)^2 - k_{0,1}^2$ , so the cut-off or lowest possible frequency for an  $E_{0,1}$  wave in an air dielectric is ( $\beta = 0$ ),

$$\omega_c/2\pi = k_{0,1}c/2\pi = 2.405 \times 3 \times 10^{10}/2\pi a = 1.15 \times 10^{10}/a$$

cycles per second if  $a$  is in centimetres. This is equivalent to a wave-length of  $2.62a$  cm. in free space.

*E waves in circular guide.* Applying the formulae in § 18.33 to (6), and including the time factor, leads to the following results:

$$E_r = A_m \frac{\beta}{k_1} J'_m(k_1 r) \cos m\theta \sin(\omega t - \beta z), \quad (9)$$

$$E_\theta = -\frac{A_m \beta m}{k_1^2 r} J_m(k_1 r) \sin m\theta \sin(\omega t - \beta z), \quad (10)$$

$$E_z = A_m J_m(k_1 r) \cos m\theta \cos(\omega t - \beta z); \quad (11)$$

$$H_r = A_m \frac{\omega \epsilon m}{k_1^2 r} J_m(k_1 r) \sin m\theta \sin(\omega t - \beta z), \quad (12)$$

$$H_\theta = A_m \frac{\omega \epsilon}{k_1} J'_m(k_1 r) \cos m\theta \sin(\omega t - \beta z), \quad (13)$$

$$H_z \equiv 0, \quad \text{by hypothesis.} \quad (14)$$

From a purely mathematical viewpoint the complete solution in each of the preceding cases involves a double summation like (1) § 16.14, in  $m$  and in  $r$  (not to be confused with  $r$  the radius). In practice, as we have seen, for any  $m$ , power is transmitted down the guide in a finite number of modes, i.e. the range of  $r$  is finite. In (9)–(13),  $k_1 = k_{m,r}$  is such that  $J_m(k_{m,r}a) = 0$ .

**18.41.  $H$  waves in circular guide.** Using (1) § 18.40 for  $H_z$ , the formal solution is identical in type with (7) § 18.40, so

$$H_{zm} = B_m J_m(k_1 r) \cos m\theta \cos(\omega t - \beta z), \quad (1)$$

where  $m = 0, 1, 2, \dots$ . From (6) § 18.34

$$E_\theta = \frac{i\mu\omega}{k_1^2} \frac{\partial H_z}{\partial r}, \quad (2)$$

and this must vanish when  $r = a$ , since  $E_\theta$  is then tangential to the inner surface of the guide. Hence  $\partial H_z / \partial r = 0$ , and from (1) with  $k'_{m,r}$  for  $k_1$  we get

$$J'_m(k'_{m,r}a) = 0. \quad (3)$$

If  $m = 0$ , the first zero occurs when  $k'_{0,1}a \simeq 3.832$ , so  $k'_{0,1} \simeq 3.832a^{-1}$ . Substituting this in (1) gives for an  $H_{0,1}$  wave

$$H_{z_{0,1}} = B_0 J_0(k'_{0,1}r) \cos(\omega t - \beta z). \quad (4)$$

The cut-off frequency ( $\beta = 0$ ) for this mode is (air-dielectric)

$$\omega_c/2\pi = k'_{0,1} c/2\pi = 3.832 \times 3 \times 10^{10}/2\pi a = 1.83 \times 10^{10}/a$$

cycles per second if  $a$  is in centimetres. This is equivalent to a wavelength of  $1.64a$  cm. in free space.

Applying the formulae in § 18.34 to (1) yields the results:

$$E_r = -B_m \frac{\mu\omega m}{k_1^2 r} J_m(k_1 r) \sin m\theta \sin(\omega t - \beta z), \quad (5)$$

$$E_\theta = -B_m \frac{\mu\omega}{k_1} J'_m(k_1 r) \cos m\theta \sin(\omega t - \beta z), \quad (6)$$

$$E_z \equiv 0, \quad \text{by hypothesis}; \quad (7)$$

$$H_r = B_m \frac{\beta}{k_1} J'_m(k_1 r) \cos m\theta \sin(\omega t - \beta z), \quad (8)$$

$$H_\theta = -B_m \frac{\beta m}{k_1^2 r} J_m(k_1 r) \sin m\theta \sin(\omega t - \beta z), \quad (9)$$

$$H_z = B_m J_m(k_1 r) \cos m\theta \cos(\omega t - \beta z). \quad (10)$$

The remarks in the last paragraph of § 18.40 are applicable here, except that now  $k_1 = k'_{m,r}$ , such that  $J'_m(k_{m,r} a) = 0$ . The lines of electric and magnetic force in a circular wave guide are depicted in Fig. 43.

**18.50. Elliptical wave guide [22].** The system of coordinates used is illustrated in Fig. 16. From § 18.30 we get  $\varphi_1 = \xi$ ,  $\varphi_2 = \eta$ ,  $\varphi_3 = z$ ,  $l_1 = l_2 = h[\frac{1}{2}(\cosh 2\xi - \cos 2\eta)]^{\frac{1}{2}}$ . Using these in (9) § 18.32 leads to the equation

$$\frac{\partial^2 E_z}{\partial \xi^2} + \frac{\partial^2 E_z}{\partial \eta^2} + \frac{1}{2} k_1^2 h^2 (\cosh 2\xi - \cos 2\eta) E_z = 0, \quad (1)$$

which has the same form as (2) § 16.20. For reasons similar to those given in § 16.11, the appropriate formal solution of (1) is

$$E_z = \sum_{m=0}^{\infty} C_m \text{Ce}_m(\xi, q) \text{ce}_m(\eta, q) + \sum_{m=1}^{\infty} S_m \text{Se}_m(\xi, q) \text{se}_m(\eta, q), \quad (2)$$

the time factor being omitted, but see (3), (4) below. For any  $m$  there are two types of solution, namely,

$$E_{z_{mc}} = C_m \text{Ce}_m(\xi, q) \text{ce}_m(\eta, q) \cos(\omega t - \beta z) \quad (3)$$

$$\text{and} \quad E_{z_{ms}} = S_m \text{Se}_m(\xi, q) \text{se}_m(\eta, q) \cos(\omega t - \beta z), \quad (4)$$

where  $k_1^2 h^2 = 4q$  and  $C_m, S_m$  are arbitrary constants determinable in

the usual way. For  $E$  waves the boundary condition is that  $E_s = 0$  at the inner surface of the guide where  $\xi = \xi_0$ . Hence we must have

$$\text{Ce}_m(\xi_0, q) = 0 \quad (5)$$

and

$$\text{Se}_m(\xi_0, q) = 0. \quad (6)$$

FIG. 43. Approximate configuration of lines of electric (—) and magnetic force (---) in circular wave guide: small solid circles represent lines of force directed towards observer. Propagation is towards the r.h.s. of page.

Let  $q_{m,r}$ ,  $\bar{q}_{m,r}$  be the respective  $r$ th roots of these equations for a given  $m$ . Then the appropriate solutions of (1) corresponding thereto are

$$E_{z_{mc}} = C_{m,r} \text{Ce}_m(\xi, q_{m,r}) \text{ce}_m(\eta, q_{m,r}) \cos(\omega t - \beta z) \quad (7)$$

and

$$E_{z_{ms}} = S_{m,r} \text{Se}_m(\xi, \bar{q}_{m,r}) \text{se}_m(\eta, \bar{q}_{m,r}) \cos(\omega t - \beta z), \quad (8)$$

where  $m \geq 0$  in (7),  $m \geq 1$  in (8), and  $r \geq 1$ . For each  $m$ , in (7)

$$\text{Ce}_m(\xi, q_{m,r}) = 0,$$

with  $r = 1, 2, \dots$ . Also for each  $r$ ,  $m$  has an infinity of values. Hence there is a double infinity of zeros. Power is transmitted down the guide only if  $\beta$  is real, so  $\omega/c > k_{m,r}$ , where  $k_{m,r}^2 h^2 = 4q_{m,r}$ , or  $k_{m,r} = 2q_{m,r}^{1/2}/ae$ . Thus for each  $m$ , power is transmitted in those modes, finite in number, for which the above inequality is satisfied. Similar remarks apply in connexion with  $\text{Se}_m(\xi, \bar{q}_{m,r})$  in (8).

For a  $\text{Ce}_m \text{ce}_m$  mode of transmission the lowest pulsance occurs when  $m = 0$ ,  $r = 1$ . Thus  $k_{0,1}^2 h^2 = 4q_{0,1}$ , so  $k_{0,1} = 2q_{0,1}^{1/2}/h = 2q_{0,1}^{1/2}/ae$  ( $e$  being the eccentricity of the ellipse), and

$$\omega_c = k_{0,1} c = 2cq_{0,1}^{1/2}/ae. \quad (9)$$

Applying the formulae in § 18.33 to (7), (8), the results for  $E$  waves are:

$$E_\xi = \frac{\beta}{k_1^2 l_1} \left\{ C_{m,r} \text{Ce}'_m(\xi, q_{m,r}) \text{ce}_m(\eta, q_{m,r}) \right\} \sin(\omega t - \beta z), \quad (10)$$

$$E_\eta = \frac{\beta}{k_1^2 l_1} \left\{ C_{m,r} \text{Ce}_m(\xi, q_{m,r}) \text{ce}'_m(\eta, q_{m,r}) \right\} \sin(\omega t - \beta z), \quad (11)$$

$$E_z = \left\{ C_{m,r} \text{Ce}_m(\xi, q_{m,r}) \text{ce}_m(\eta, q_{m,r}) \right\} \cos(\omega t - \beta z); \quad (12)$$

$$H_\xi = -\frac{\omega \epsilon}{\beta} E_\eta, \quad (13)$$

$$H_\eta = \frac{\omega \epsilon}{\beta} E_\xi, \quad (14)$$

$$H_z \equiv 0, \quad \text{by hypothesis.} \quad (15)$$

The respective arbitrary constants in (10)–(14) are the same. Convenient symbols for  $E$ -wave modes are  $E_{cm,r}$ ,  $E_{sm,r}$ ,  $m$ ,  $r$  having the values stated below (8), so that  $\omega/c > k_{m,r}$  or  $\bar{k}_{m,r}$ .

**18.51.  $H$  waves in elliptical guide.** Here  $E_z \equiv 0$  by hypothesis, and  $H_z$  satisfies an equation like (1) § 18.50. Thus the formal solution for the  $m$ th mode is

$$H_z = \left\{ \bar{C}_m \text{Ce}_m(\xi, q) \text{ce}_m(\eta, q) \right\} \cos(\omega t - \beta z). \quad (1)$$

The tangential component of  $E$  must vanish at the inner surface of the guide, so  $E_\eta = 0$  when  $\xi = \xi_0$ . Then by (6) § 18.34, since  $\varphi_1 = \xi$ , it follows that

$$\left[ \frac{\partial H_z}{\partial \xi} \right]_{\xi=\xi_0} = 0, \quad \text{so } \text{Ce}'_m(\xi_0, q) = 0, \quad (2)$$

$$\text{and } \text{Se}'_m(\xi_0, q) = 0. \quad (3)$$

Let  $q_{m,p}$ ,  $\bar{q}_{m,p}$  be the respective  $p$ th roots of these equations for a given  $m$ . Then the appropriate solutions of the differential equation corresponding to the  $p$ th modes are

$$H_z = \left\{ \bar{C}_{m,p} \text{Ce}_m(\xi, q_{m,p}) \text{ce}_m(\eta, q_{m,p}) \right\} \cos(\omega t - \beta z), \quad (4)$$

$$\left\{ \bar{S}_{m,p} \text{Se}_m(\xi, \bar{q}_{m,p}) \text{se}_m(\eta, \bar{q}_{m,p}) \right\}$$

with  $m \geq 0$  for  $\text{Ce}_m \text{ce}_m$ ,  $m \geq 1$  for  $\text{Se}_m \text{se}_m$ , and  $p \geq 1$ , such that

FIG. 44. Lines of electric (—) and magnetic force (---) in elliptical wave guide: eccentricity of ellipse is 0.75. (A)  $H_{s1,1}$  wave; (B)  $E_{s1,1}$  wave.

$\omega/c > k_{m,p}$  or  $\bar{k}_{m,p}$ . The lowest pulsatace is obtained by the procedure given in § 16.23. Applying the formulae in § 18.34 to (4), the results for  $H$  waves are:

$$E_\xi = \frac{\mu\omega}{k_1^2 l_1} \left\{ \bar{C}_{m,p} \text{Ce}_m(\xi, q_{m,p}) \text{ce}'_m(\eta, q_{m,p}) \right\} \sin(\omega t - \beta z), \quad (5)$$

$$\left\{ \bar{S}_{m,p} \text{Se}_m(\xi, \bar{q}_{m,p}) \text{se}'_m(\eta, \bar{q}_{m,p}) \right\}$$

$$E_\eta = -\frac{\mu\omega}{k_1^2 l_1} \left\{ \bar{C}_{m,p} \text{Ce}'_m(\xi, q_{m,p}) \text{ce}_m(\eta, q_{m,p}) \right\} \sin(\omega t - \beta z), \quad (6)$$

$$\left\{ \bar{S}_{m,p} \text{Se}'_m(\xi, \bar{q}_{m,p}) \text{se}_m(\eta, \bar{q}_{m,p}) \right\}$$

$$E_z \equiv 0; \quad (7)$$

$$H_\xi = -\frac{\beta}{\mu\omega} E_\eta, \quad (8)$$

$$H_\eta = \frac{\beta}{\mu\omega} E_\xi, \quad (9)$$

$$H_z \text{ as at (4) above.} \quad (10)$$

The constants  $\bar{C}_{m,p}$ ,  $\bar{S}_{m,p}$  are the same throughout. Convenient symbols for  $H$  waves are  $H_{cm,p}$ ,  $H_{sm,p}$ ,  $m$ ,  $p$  having the values given below (4).

The lines of electric and magnetic force in an elliptical wave guide are portrayed in Fig. 44.

**18.52. Power transmitted down elliptical wave guide.** The power passing through each unit area of cross-section in the direction of the  $z$ -axis, i.e. the time rate of energy flow per unit area, may be calculated by aid of the Poynting vector  $\mathbf{p}$ . If  $\mathbf{E}$ ,  $\mathbf{H}$  are the electric and magnetic force vectors at any point  $(\xi, \eta)$  in the cross-section, then

$$\mathbf{p} = \mathbf{E}\mathbf{H}/4\pi, \quad (1)$$

where the vector product is to be taken. Expressed in terms of scalar quantities

$$p_z = \frac{1}{4\pi} [E_\xi H_\eta - E_\eta H_\xi]. \quad (2)$$

Substituting from (10), (11), (13), (14) § 18.50 for the various quantities, (2) becomes

$$p_z = \frac{1}{4\pi} \frac{\beta\omega\epsilon}{k_1^4 l_1^2} |C_m|^2 [C e_m'^2(\xi, q_{m,r}) c e_m^2(\eta, q_{m,r}) + C e_m^2(\xi, q_{m,r}) c e_m'^2(\eta, q_{m,r})] \sin^2(\omega t - \beta z) \quad (3)$$

for an  $E_{cm,r}$  type of wave,  $C_m$  being a constant. The mean power transmitted through unit area, taken over a cycle of  $\sin \omega t$  at any  $z$ , is one-half the maximum value of (3). Hence the total mean power for the  $m$  mode in question is found by omitting  $\sin^2(\omega t - \beta z)$  and halving the integral of (3) over the cross-section. Thus, omitting  $q_{m,r}$  for brevity,

$$P_z = \frac{|C_m|^2 \beta \omega \epsilon}{8\pi k_1^4} \iint [C e_m'^2(\xi) c e_m^2(\eta) + C e_m^2(\xi) c e_m'^2(\eta)] \frac{ds_1 ds_2}{l_1^2}, \quad (4)$$

$ds_1$ ,  $ds_2$ , and  $l_1$  being defined in § 9.12. But  $ds_1 ds_2 / l_1^2 = d\xi d\eta$ , so (4) may be written

$$P_z = \frac{|C_m|^2 \beta \omega \epsilon}{8\pi k_1^4} \int_0^{\xi_0} \int_0^{2\pi} [C e_m'^2(\xi) c e_m^2(\eta) + C e_m^2(\xi) c e_m'^2(\eta)] d\xi d\eta. \quad (5)$$

By (1) § 2.21,  $\int_0^{2\pi} c e_m^2(\eta) d\eta = \pi$ , and by (3) § 14.41,  $\int_0^{2\pi} c e_m'^2(\eta) d\eta = \vartheta_m \pi$ .

$$\text{Thus} \quad P_z = \frac{|C_m|^2 \beta \omega \epsilon}{8k_1^4} \int_0^{\xi_0} [C e_m'^2(\xi, q_{m,r}) + \vartheta_m C e_m^2(\xi, q_{m,r})] d\xi. \quad (6)$$

For an  $E_{sm,r}$  type of wave,  $P_z$  is given by (6) on replacing  $C e_m$  by  $S e_m$ ,  $q_{m,r}$  by  $\bar{q}_{m,r}$ , and  $\vartheta_m$  by  $\varpi_m$ . Formulae for  $H$  waves are obtained from (6) if  $\epsilon$  is replaced by  $\mu$ , and  $q_{m,r}$ ,  $\bar{q}_{m,r}$  by  $q_{m,p}$ ,  $\bar{q}_{m,p}$ , respectively.

**18.53. Attenuation of waves due to imperfect conductor [199].** Hitherto the metal of the guide has been assumed a perfect conductor, so that waves travel from end to end without loss. In practice, however, loss must be taken into account. We confine our attention to metallic loss and assume absence of loss in the air dielectric. If the resistivity of the metal is included in Maxwell's

FIG. 45. Illustrating penetration of current into very large flat slab, induced by sinusoidally varying magnetic field tangential to free surface.

equations the loss may be determined, but not without undue complication. It is adequate for practical purposes to assume that the magnetic field at the inner surface of the guide is the same as it would be if the metal had zero resistivity. Then introducing  $\rho_1 > 0$  into the analysis, we calculate the eddy-current loss as in the case of a metal slab.

Consider a very large metal slab of resistivity  $\rho_1$  whose upper face lies in the  $XZ$  plane, Fig. 45. Let a cosinusoidal electromagnetic field exist above the slab, the maximum value of the magnetic component tangential thereto being  $H_t$ . This induces a *surface* current of density  $\sigma$  in a *non-resistive* slab, such that

$$H_t = 4\pi\sigma, \quad \text{or} \quad \sigma = H_t/4\pi. \quad (1)$$

Since  $\rho_1 > 0$  in practice, there is a *volume* distribution of current whose density at a depth  $y$  below the surface is  $\sigma_1$ . This depends upon  $\rho_1$ , the magnetic permeability  $\mu_1$ , and  $f$  the frequency of the electromagnetic field. The propagation of power *into* the slab perpendicular to its surface is similar to that along a uniform trans-

mission line. If  $\sigma_0 \cos \omega t$  is the surface-current density, it may be shown that at any depth  $y$  below the surface

$$\sigma_1 = \sigma_0 e^{-\beta_1 y} \cos(\omega t - \beta_1 y), \quad (2)$$

where  $\beta_1 = 2\pi(\mu_1 f / \rho_1)^{\frac{1}{2}}$ . We have now to determine  $\sigma_0$ , so that the volume distribution of current in the slab is equal to  $\sigma$ , i.e.

$$\text{maximum value of } \int_0^\infty \sigma_1 dy = H_l / 4\pi. \quad (3)$$

Substituting from (2) for  $\sigma_1$  into the integral in (3) and evaluating yields†  $\sigma_0 \cos(\omega t - \frac{1}{2}\pi) / 2^{\frac{1}{2}} \beta_1$ . The angle  $\frac{1}{2}\pi$  is due to the current not being in phase throughout the depth of the slab. The loss is unaffected by omitting  $\frac{1}{2}\pi$ , so equating the maximum values in (3) leads to  $\sigma_0 = \beta_1 H_l / 2^{\frac{1}{2}} \pi$ . Thus the equivalent root mean square value of  $\sigma_1$  in (2) is

$$\sigma_{r.m.s.} = \beta_1 H_l e^{-\beta_1 y} / 4\pi. \quad (4)$$

Then the power loss per unit surface area of the slab is given by

$$\rho_1 \int_0^\infty \sigma_{r.m.s.}^2 dy = \frac{\rho_1 \beta_1^2 H_l^2}{16\pi^2} \int_0^\infty e^{-2\beta_1 y} dy, \quad (5)$$

$$\text{so} \quad P_{cm.s.} = \beta_1 \rho_1 H_l^2 / 32\pi^2 = (\mu_1 \rho_1 f)^{\frac{1}{2}} H_l^2 / 16\pi. \quad (6)$$

Since the depth of penetration into the metal of a guide at ultra high frequency is very small, the preceding analysis is applicable to curved surfaces, provided the curvature is not excessive. This condition obtains in practical wave guides where the ratio (depth of penetration/radius of curvature) is of the order  $2 \times 10^{-5}$  or less, except in the region of a corner. The proportionate surface area affected is then quite small.

**18.54. Application of analysis in § 18.53 to wave guide.** If  $ds$  is an elemental arc-length of a cross-section at the inner surface of the guide, the area of a surface element of unit axial length is  $dA = ds \times 1$ . The magnetic field component tangential to the element is  $H_t$ . Then by (6) § 18.53 the power loss in the element is  $dP = (\mu_1 \rho_1 f)^{\frac{1}{2}} H_t^2 ds / 16\pi$ , so the total loss in unit length of the guide is

$$P = \frac{1}{16\pi} (\mu_1 \rho_1 f)^{\frac{1}{2}} \int H_t^2 ds, \quad (1)$$

the integration being taken round the inner surface.

$$\dagger \int_0^\infty e^{-\beta_1 y} \cos(\beta_1 y - \alpha_1) dy = \frac{1}{2\beta_1} (\cos \alpha_1 + \sin \alpha_1) = \frac{1}{2^{\frac{1}{2}} \beta_1} \cos(\alpha_1 - \frac{1}{2}\pi).$$

As the waves travel down the guide, the power absorbed by the metal per unit length is given by (1). Consequently it represents  $-dP_z/dz$ ,† the distance rate of power loss sustained by the waves. If we define this loss to be

$$P = -dP_z/dz = 2\alpha P_z, \quad (2)$$

then  $\alpha$  is known as the attenuation constant. The multiplier 2 arises as follows: If  $H_m$  is the maximum magnetic field at the transmitter where  $z = 0$ , its value at a point  $z > 0$  is  $H_m e^{-\alpha z}$ . The power, however, is proportional to  $(H_m e^{-\alpha z})^2 = H_m^2 e^{-2\alpha z}$ , i.e.  $P_z = P_m e^{-2\alpha z}$ , so

$$-dP_z/dz = 2\alpha P_m e^{-2\alpha z} = 2\alpha P_z, \quad (3)$$

$$\text{giving} \quad \alpha = P/2P_z. \quad (4)$$

For purposes of calculation the value of  $z$  is immaterial, since  $\alpha$  is constant.

**18.55. Attenuation in elliptical wave guide.** For an  $E_{cm,r}$  type of wave the tangential component of magnetic force at the inner surface of the guide, where  $\xi = \xi_0$ , is

$$H_\eta = \frac{C_m \omega \epsilon}{k_1^2 l_1} \text{Ce}'_m(\xi_0, q_{m,r}) \text{ce}_m(\eta, q_{m,r}), \quad (1)$$

$C_m$  being a constant.

Also by § 9.12,  $ds = l_1 d\eta$ , so by aid of (1) § 18.54 we get the loss per unit length as

$$P = |C_m|^2 \frac{(\mu_1 \rho_1 f)^{\frac{1}{2}} \omega^2 \epsilon^2}{16\pi k_1^4} [\text{Ce}_m'^2(\xi_0, q_{m,r})] \int_0^{2\pi} \text{ce}_m^2(\eta, q_{m,r}) d\eta / l_1. \quad (2)$$

Now

$$\begin{aligned} l_1 &= h(\cosh^2 \xi - \cos^2 \eta)^{\frac{1}{2}} = h \cosh \xi_0 [1 - (\cos \eta / \cosh \xi_0)^2]^{\frac{1}{2}} \\ &= a(1 - e^2 \cos^2 \eta)^{\frac{1}{2}}, \end{aligned}$$

$e$  being the eccentricity of the bounding ellipse. Substituting this value of  $l_1$  into (2) leads to

$$P = |C_m|^2 \frac{(\mu_1 \rho_1 f)^{\frac{1}{2}} \omega^2 \epsilon^2}{16\pi a k_1^4} [\text{Ce}_m'^2(\xi_0, q_{m,r})] \int_0^{2\pi} \text{ce}_m^2(\eta, q_{m,r}) d\eta / (1 - e^2 \cos^2 \eta)^{\frac{1}{2}}. \quad (3)$$

† The negative sign indicates decrease in  $P_z$  with increase in  $z$ .  $P_z$  is the total power passing a section distant  $z$  from the transmitter.

Since  $e < 1$ , the denominator of the integrand may be expanded binomially, and we get for the integral

$$I = \int_0^{2\pi} \text{ce}_m^2(\eta, q_{m,r}) \times \left[ 1 + \frac{1}{2}e^2 \cos^2 \eta + \frac{1 \cdot 3}{2^2 \cdot 2!} e^4 \cos^4 \eta + \frac{1 \cdot 3 \cdot 5}{2^3 \cdot 3!} e^6 \cos^6 \eta + \dots \right] d\eta. \quad (4)$$

On substituting the series for  $\text{ce}_{2n}(\eta, q_{2n,r})$  in (4) and using (9) § 9.40, we obtain

$$I = \pi \left[ 1 + \frac{1}{2^2} e^2 \{1 + \Theta_{2n}\} + \dots \right]. \quad (5)$$

Inserting (5) into (3), with  $m = 2n$  the expression for the power loss per unit length of guide is

$$P = |C_{2n}|^2 \frac{(\mu_1 \rho_1 f)^{\frac{1}{2}} \omega^2 \epsilon^2}{16 a k_1^4} [\text{Ce}_{2n}'^2(\xi_0, q_{2n,r})] \left[ 1 + \frac{1}{2^2} e^2 \{1 + \Theta_{2n}\} + \dots \right]. \quad (6)$$

From (6) § 18.52 and (6) above, the attenuation constant is

$$\alpha = \frac{1}{4a} \left( \frac{\mu_1 \rho_1 f \epsilon}{\mu} \right)^{\frac{1}{2}} \frac{\text{Ce}_{2n}'^2(\xi_0, q_{2n,r})}{[1 - (f_c/f)^2]^{\frac{1}{2}}} \frac{\left[ 1 + \frac{1}{2^2} e^2 \{1 + \Theta_{2n}\} + \dots \right]}{\int_0^{\xi_0} [\text{Ce}_{2n}'^2(\xi, q_{2n,r}) + \vartheta_{2n} \text{Ce}_{2n}^2(\xi, q_{2n,r})] d\xi}. \quad (7)$$

In (7)  $f_c$  is the cut-off frequency.

For  $H_{cm}$  waves the attenuation constant may be shown to be

$$\alpha = \frac{(\mu_1 \rho_1 f)^{\frac{1}{2}}}{4\pi a \beta \mu \omega} \text{Ce}_m^2(\xi_0, q_{m,p}) \times \frac{\left[ \beta^2 \int_0^{2\pi} \frac{\text{ce}_m^2(\eta, q_{m,p}) d\eta}{(1 - e^2 \cos^2 \eta)^{\frac{1}{2}}} + k_1^4 a^2 \int_0^{2\pi} \text{ce}_m^2(\eta, q_{m,p}) (1 - e^2 \cos^2 \eta)^{\frac{1}{2}} d\eta \right]}{\int_0^{\xi_0} [\text{Ce}_m'^2(\xi, q_{m,p}) + \vartheta_m \text{Ce}_m^2(\xi, q_{m,p})] d\xi}, \quad (8)$$

which may be evaluated by procedure akin to that above (7), a numerical process being used for the denominator.

**18.56. Transition to circular cross-section.** The results in Appendix I may be used to reproduce the formulae for a circular section given in §§ 18.40, 18.41 from those in §§ 18.50, 18.51.

**18.57. Influence of deviation of cross-section from circularity [22, 199].** Using the formulae in (12) § 18.50, when the ellipse tends towards a circle, by Appendix I—omitting the time factor—we have

$$E_{z_{cm}} = C_m Ce_m(\xi, q_{m,r}) ce_m(\eta, q_{m,r}) \rightarrow C_m p'_m J_m(k_1 r) \cos m\theta, \quad (1)$$

for an  $E_{cm}$  type wave, and

$$E_{z_{sm}} = S_m Se_m(\xi, \bar{q}_{m,r}) se_m(\eta, \bar{q}_{m,r}) \rightarrow S_m s'_m J_m(k_1 r) \sin m\theta, \quad (2)$$

for an  $E_{sm}$  type wave. Consider both solutions in (5) § 18.40 for

FIG. 46. (A, B) Illustrating deformation of circular wave guide to elliptical form.

waves in a circular guide for the modes  $m = 1, r = 1, 2, \dots$ , and suppose that the deformation occurs in the position shown in Fig. 46 A. If the orientation of the wave—looking down the guide—is such that  $S_1 = 0$ , then

$$E_z = C_1 p'_1 J_1(k_1 r) \cos \theta \leftarrow C_1 Ce_1(\xi, q_{1,r}) ce_1(\eta, q_{1,r}) \quad (3)$$

and at the deformation the wave will tend to an  $E_{c1}$  type. In the same way, if the deformation occurs as shown in Fig. 46 B, i.e.  $\frac{1}{2}\pi$  away from the position indicated in Fig. 46 A, and the orientation of the wave is such that  $C_1 = 0$ ,

$$E_z = S_1 s'_1 J_1(k_1 r) \sin \theta \leftarrow S_1 Se_1(\xi, \bar{q}_{1,r}) se_1(\eta, \bar{q}_{1,r}), \quad (4)$$

so the wave will tend to an  $E_{s1}$  type. Generally the deformation will occur in a position such that neither  $C_1$  nor  $S_1$  is zero, so that both  $E_{c1}, E_{s1}$  waves may be created. Now these corresponding types

have different phase velocities.† Consequently in travelling down the guide the two waves will fall out of step progressively. It follows, therefore, that unless  $C_1 = S_1 = 0$ , i.e. the deformation occurs along an axis of symmetry of the wave pattern (see Fig. 44), non-circularity introduces a degree of instability. Since there is no  $E_{sm}$  wave of order  $m = 0$ , slight deformation will not cause splitting of an  $E_0$  wave. For  $m = 1, 2, \dots$  splitting of the wave into two components with unequal phase velocities will occur. Similar conclusions apply for  $H$  waves. It may be remarked that with an  $E_1$  or an  $H_1$  wave, after splitting occurs, one component has a higher attenuation than the other, and after travelling an adequate distance down the guide, the component with the greater attenuation will be of negligible comparative amplitude.

† From § 18.24,  $\beta^2 = (\omega/c)^2 - (\omega_c/c)^2$ , so  $\beta = (\omega/c)[1 - (\omega_c/\omega)^2]^{\frac{1}{2}}$ , where  $\omega_c/2\pi$  is the cut-off frequency for the transmission mode concerned. The phase velocity is  $v_p = \omega/\beta = c[1 - (\omega_c/\omega)^2]^{-\frac{1}{2}}$ . As  $\omega \rightarrow \omega_c + 0$ ,  $v_p \rightarrow +\infty$ , which is a well-known phenomenon in geometrical optics. By the principle of relativity, no *actual* velocity can exceed that of light, so that phase velocity must be regarded as a useful fiction!

## XIX

### DIFFRACTION OF SOUND AND ELECTROMAGNETIC WAVES

**19.10. Scattering of sound by elliptical cylinder.** Referring to Fig. 47, a plane sound wave in air travels towards the origin from the lower side and impinges at an angle  $\theta$  on a right elliptical cylinder with axis  $Z'OZ$ , normal to the plane of the paper. The cylinder is long compared with its major axis, being immobile and non-absorbent. Its presence causes the sound to be scattered.

Analytically we may for convenience consider the wave to have two components. There is (1) a plane wave identical with that in absence of the cylinder, (2) a scattered wave, diverging away from  $O$ , for which we have to derive a symbolical representation.

**19.11. Equation of sound propagation.** The two-dimensional equation is

$$\frac{\partial^2 \phi}{\partial x^2} + \frac{\partial^2 \phi}{\partial y^2} + k_1^2 \phi = 0, \quad (1)$$

where  $\phi$  is the velocity potential,  $k_1 = \omega/c$ , and  $c$  is the velocity of sound in the medium [see reference 201, chap. ii]. Since we are dealing with an elliptical cylinder, we transform (1) to elliptical coordinates. Thus by § 9.20 we obtain

$$\frac{\partial^2 \phi}{\partial \xi^2} + \frac{\partial^2 \phi}{\partial \eta^2} + 2k^2 (\cosh 2\xi - \cos 2\eta) \phi = 0, \quad (2)$$

with  $2k = k_1 h$ .

**19.12. Velocity potential of plane wave.** For a plane wave travelling as shown in Fig. 47 the root mean square value† of the velocity potential at any point on the wave front at a perpendicular distance  $\rho$  from the origin  $O$ , in absence of the cylinder, is represented by

$$\phi_1 = \phi_0 e^{i(k_1 \rho - \omega t)}. \quad (1)$$

From Fig. 47

$$\rho = x \cos \theta + y \sin \theta, \quad (2)$$

† Sinusoidal variation implied.

and by (7) § 10.53, (1) expressed in elliptical coordinates is

$$\begin{aligned} \phi_1 = & 2\phi_0 e^{-i\omega t} \times \\ & \times \sum_{n=0}^{\infty} \left[ \frac{1}{p_{2n}} \text{Ce}_{2n}(\xi) \text{ce}_{2n}(\eta) \text{ce}_{2n}(\theta) + \frac{1}{s_{2n+2}} \text{Se}_{2n+2}(\xi) \text{se}_{2n+2}(\eta) \text{se}_{2n+2}(\theta) + \right. \\ & \left. + i \left\{ \frac{1}{p_{2n+1}} \text{Ce}_{2n+1}(\xi) \text{ce}_{2n+1}(\eta) \text{ce}_{2n+1}(\theta) + \frac{1}{s_{2n+1}} \text{Se}_{2n+1}(\xi) \text{se}_{2n+1}(\eta) \text{se}_{2n+1}(\theta) \right\} \right]. \end{aligned} \quad (3)$$

FIG. 47. Illustrating plane wave impinging upon very long rigid cylinder.  $Q$  has coordinates  $\xi, \eta$  defined by orthogonal intersection of confocal ellipse and hyperbola.

$$ON = x, \quad NQ = y, \quad OM = x \cos \theta, \quad MP = y \sin \theta,$$

$$\rho = OP = x \cos \theta + y \sin \theta = h(\cosh \xi \cos \eta \cos \theta + \sinh \xi \sin \eta \sin \theta).$$

$F_1, F_2$  are foci and  $F_1 F_2 = 2h$ .  $MN$  and  $PQ$  are perpendicular to  $OP$ .

This is a solution of (2) § 19.11 and represents the velocity potential of the plane wave in absence of the cylinder.

**19.13. Boundary conditions.** Since the surface of the cylinder is immobile, the velocity of the air particles normal thereto must be zero. Thus the first boundary condition is that the sum of the normal velocities of the incident and scattered waves shall vanish at  $\xi = \xi_0$ . If  $u_{n_1}$  is the normal velocity of the incident wave and  $u_{n_2}$  that of the scattered wave, whose velocity potential is  $\phi_2$ , we must have

$$u_{n_1} + u_{n_2} = -\left(\frac{\partial \phi_1}{\partial n} + \frac{\partial \phi_2}{\partial n}\right)_{\xi=\xi_0} = 0, \quad (1)$$

$n$  indicating the direction of the normal. From § 9.12  $\partial n = l_1 \partial \xi$ , so the first boundary condition may be written

$$\left( \frac{\partial \phi_1}{\partial \xi} + \frac{\partial \phi_2}{\partial \xi} \right)_{\xi=\xi_0} = 0. \quad (2)$$

The second boundary condition is

$$\phi_2 \rightarrow 0 \quad \text{as} \quad \xi \rightarrow +\infty, \quad (3)$$

since the influence of the cylinder is nil at infinity.

**19.14. Representation of scattered wave.** Being different from the incident plane wave, the scattered wave cannot be represented by (3) § 19.12. Accordingly we have to choose an expression which (a) represents propagation of the scattered wave in the direction indicated in Fig. 47, (b) is a solution of (2) § 19.11, (c) permits the first boundary condition to be satisfied, (d) satisfies the second boundary condition. The solution selected comprises two sets of  $\sum$  terms, each set having an infinite number of component solutions. For the  $m$ th term of the first set, if we take

$$\psi_{c_m} = C_m e^{-i\omega t} \text{Me}_m^{(1)}(\xi, q) \text{ce}_m(\eta, q) \text{ce}_m(\theta, q), \quad (1)$$

$C_m$  being a complex constant, all the above conditions are satisfied. Since  $\text{Me}_m^{(1)} = \text{Ce}_m + i \text{Fe}_m$ , (1) represents a wave moving as shown in Fig. 47. We shall see later that the first boundary condition may be satisfied if  $C_m$  is correctly chosen. From the asymptotic formulae for  $\text{Me}_m^{(1)}(\xi)$  in § 11.11 it is seen that  $\psi_{c_m} \rightarrow 0$  as  $\xi \rightarrow +\infty$ .

In the second set of  $\sum$  terms in the proposed solution we incorporate the function  $\text{Ne}_m^{(1)} = \text{Se}_m + i \text{Ge}_m$ . The required form of solution which represents wave propagation away from the origin as in Fig. 47, is

$$\psi_{s_m} = S_m e^{-i\omega t} \text{Ne}_m^{(1)}(\xi, q) \text{se}_m(\eta, q) \text{se}_m(\theta, q), \quad (2)$$

which has the properties (a)–(d) given above. Thus for the scattered wave we take the solution

$$\begin{aligned} \phi_2 = & e^{-i\omega t} \times \\ & \times \sum_{n=0}^{\infty} [C_{2n} \text{Me}_{2n}^{(1)}(\xi) \text{ce}_{2n}(\eta) \text{ce}_{2n}(\theta) + C_{2n+1} \text{Me}_{2n+1}^{(1)}(\xi) \text{ce}_{2n+1}(\eta) \text{ce}_{2n+1}(\theta) + \\ & + S_{2n+1} \text{Ne}_{2n+1}^{(1)}(\xi) \text{se}_{2n+1}(\eta) \text{se}_{2n+1}(\theta) + \\ & + S_{2n+2} \text{Ne}_{2n+2}^{(1)}(\xi) \text{se}_{2n+2}(\eta) \text{se}_{2n+2}(\theta)]. \quad (3) \end{aligned}$$

Using condition (2) § 19.13 and equating the sum of the derivatives of functions of the same kind and order to zero, gives for  $\xi = \xi_0$ :

$$C_{2n} = -\frac{2\phi_0}{p_{2n}} \frac{Ce'_{2n}(\xi_0)}{Me^{(1)'}_{2n}(\xi_0)} = -\frac{2\phi_0 \cos \alpha_{2n} e^{-i\alpha_{2n}}}{p_{2n}}, \quad (4)$$

where  $\cos \alpha_{2n} = Ce'_{2n}(\xi_0)/[Ce'^2_{2n}(\xi_0) + Fey'^2_{2n}(\xi_0)]^\dagger$ ;

$$C_{2n+1} = -\frac{2i\phi_0}{p_{2n+1}} \frac{Ce'_{2n+1}(\xi_0)}{Me^{(1)'}_{2n+1}(\xi_0)} = -\frac{2\phi_0 \cos \alpha_{2n+1} e^{-i(\alpha_{2n+1} - \frac{1}{2}\pi)}}{p_{2n+1}}, \quad (5)$$

where  $\cos \alpha_{2n+1} = Ce'_{2n+1}(\xi_0)/[Ce'^2_{2n+1}(\xi_0) + Fey'^2_{2n+1}(\xi_0)]^\dagger$ ;

$$S_{2n+1} = -\frac{2i\phi_0}{s_{2n+1}} \frac{Se'_{2n+1}(\xi_0)}{Ne^{(1)'}_{2n+1}(\xi_0)} = -\frac{2\phi_0 \cos \beta_{2n+1} e^{-i(\beta_{2n+1} - \frac{1}{2}\pi)}}{s_{2n+1}}, \quad (6)$$

where  $\cos \beta_{2n+1} = Se'_{2n+1}(\xi_0)/[Se'^2_{2n+1}(\xi_0) + Gey'^2_{2n+1}(\xi_0)]^\dagger$ ;

$$S_{2n+2} = -\frac{2\phi_0}{s_{2n+2}} \frac{Se'_{2n+2}(\xi_0)}{Ne^{(1)'}_{2n+2}(\xi_0)} = -\frac{2\phi_0 \cos \beta_{2n+2} e^{-i\beta_{2n+2}}}{s_{2n+2}}, \quad (7)$$

where  $\cos \beta_{2n+2} = Se'_{2n+2}(\xi_0)/[Se'^2_{2n+2}(\xi_0) + Gey'^2_{2n+2}(\xi_0)]^\dagger$ , and  $p_m, s_m$  are defined in Appendix I.

The velocity potential at any point on or outside the cylinder is

$$\begin{aligned} \phi &= \phi_1 + \phi_2 \\ &= \phi_0 e^{i(k_1 \rho - \omega t)} + \phi_2 \quad [\text{as at (3) above}]. \end{aligned} \quad (8)$$

This may be regarded as a general solution of the problem. If  $\theta = 0$ , and the incident wave travels parallel to the  $X$ -axis, the terms in (3) involving  $S_{2n+1}, S_{2n+2}$  vanish, leaving

$$\phi_2 = e^{-i\omega t} \sum_{m=0}^{\infty} C_m Me^{(1)}_m(\xi) ce_m(\eta) ce_m(0). \quad (9)$$

When  $\theta = \frac{1}{2}\pi$ , the incident wave travels parallel to the  $Y$ -axis, and we get

$$\begin{aligned} \phi_2 &= e^{-i\omega t} \sum_{n=0}^{\infty} [C_{2n} Me^{(1)}_{2n}(\xi) ce_{2n}(\eta) ce_{2n}(\tfrac{1}{2}\pi) + \\ &\quad + S_{2n+1} Ne^{(1)}_{2n+1}(\xi) se_{2n+1}(\eta) se_{2n+1}(\tfrac{1}{2}\pi)]. \end{aligned} \quad (10)$$

**19.20. Long rigid ribbon.** This case is obtained when  $\xi_0 \rightarrow 0$ , the width of the ellipse of evanescent minor axis then tending to  $2h$ , the interfocal distance. When  $\xi_0 = 0$ ,  $Ce'_m(\xi_0) = 0$ , and in (3) § 19.14  $C_{2n} = C_{2n+1} = 0$ , while

$$S_{2n+1} = -2i\phi_0 k B_1^{(2n+1)}/se_{2n+1}(\tfrac{1}{2}\pi) Ne^{(1)'}_{2n+1}(0) \quad (1)$$

and

$$S_{2n+2} = -2\phi_0 k^2 B_2^{(2n+2)}/se'_{2n+2}(\tfrac{1}{2}\pi) Ne^{(1)'}_{2n+2}(0). \quad (2)$$

Inserting these in (3) § 19.14 we obtain the velocity potential of the scattered wave at any point, whose coordinates are  $\xi$ ,  $\eta$ , on or outside the ribbon. Thus

$$\phi_2 = -2e^{-i\omega t}\phi_0 k \sum_{n=0}^{\infty} \left[ iB_1^{(2n+1)} \frac{\text{Ne}_{2n+1}^{(1)}(\xi)\text{se}_{2n+1}(\eta)\text{se}_{2n+1}(\theta)}{\text{se}_{2n+1}(\frac{1}{2}\pi, q)\text{Ne}_{2n+1}^{(1)'}(0)} + \right. \\ \left. + kB_2^{(2n+2)} \frac{\text{Ne}_{2n+2}^{(1)}(\xi)\text{se}_{2n+2}(\eta)\text{se}_{2n+2}(\theta)}{\text{se}_{2n+2}'(\frac{1}{2}\pi, q)\text{Ne}_{2n+2}^{(1)'}(0)} \right]. \quad (3)$$

At the surface of the ribbon  $\xi = 0$ , so by (3) § 19.12 the velocity potential due to the plane wave is

$$\phi_1 = 2e^{-i\omega t}\phi_0 \sum_{n=0}^{\infty} \left[ \frac{A_0^{(2n)} \text{ce}_{2n}(\eta)\text{ce}_{2n}(\theta)}{\text{ce}_{2n}(\frac{1}{2}\pi, q)} - \frac{ikA_1^{(2n+1)} \text{ce}_{2n+1}(\eta)\text{ce}_{2n+1}(\theta)}{\text{ce}_{2n+1}'(\frac{1}{2}\pi, q)} \right]. \quad (4)$$

Since  $\text{Se}_m(0) = 0$ , by (3) above the velocity potential due to the scattered wave is

$$\phi_2 = 2e^{-i\omega t}\phi_0 k \sum_{n=0}^{\infty} \left[ \frac{B_1^{(2n+1)} \text{Gey}_{2n+1}(0)\text{se}_{2n+1}(\eta)\text{se}_{2n+1}(\theta)}{\text{Ne}_{2n+1}^{(1)'}(0)\text{se}_{2n+1}(\frac{1}{2}\pi, q)} - \right. \\ \left. - \frac{ikB_2^{(2n+2)} \text{Gey}_{2n+2}(0)\text{se}_{2n+2}(\eta)\text{se}_{2n+2}(\theta)}{\text{Ne}_{2n+2}^{(1)'}(0)\text{se}_{2n+2}'(\frac{1}{2}\pi, q)} \right]. \quad (5)$$

The resultant velocity potential at the ribbon surface due to both the incident and scattered waves is the sum of (4) and (5). If  $p_0$  is the root mean square pressure of the incident wave, then, since  $p = \rho_0 \partial \phi / \partial t = -i\rho\omega\phi$ ,† the pressure is obtained from (4), (5) by writing  $p_0$  for  $\phi_0$ ,  $p_1$ ,  $p_2$  for  $\phi_1$ ,  $\phi_2$ , respectively.

Polar diagrams for plane sound waves scattered by a ribbon of width  $2h$  for various wave-lengths (as a function of  $2h$ ) and angles of incidence are shown in Fig. 48.

The solution for the diffraction of sound waves at a slit of width  $2h$  in an infinite rigid plane may be obtained by analysis akin to that above, but the boundary condition corresponding to (2) § 19.13 is now that the velocity of the sound waves normal to the plane is zero.

†  $\rho_0$  is the density of the undisturbed medium, while  $p$  is not to be confused with the multipliers in (4), (5), § 19.14.

FIG. 48. Polar diagrams for sound scattered by a long ribbon [144].

**19.21. Formulae for large distance from ribbon.** The confocal ellipses are now sensibly concentric circles, and we may use the asymptotic formulae for the Ne functions, with  $k_1 r = v$  (see § 9.12 and Appendix I). Thus from (3), (4) § 11.11, if  $|v| \gg n$ ,

$$\text{Ne}_{2n+1}^{(1)}(\xi) \sim -\frac{\text{se}_{2n+1}'(0)\text{se}_{2n+1}(\frac{1}{2}\pi)}{k B_1^{(2n+1)}} \left(\frac{2}{\pi v}\right)^{\frac{1}{2}} e^{i(v+\frac{1}{2}\pi)} \quad (1)$$

and 
$$\text{Ne}_{2n+2}^{(1)}(\xi) \sim -i \frac{\text{se}_{2n+2}'(0)\text{se}_{2n+2}(\frac{1}{2}\pi)}{k^2 B_2^{(2n+2)}} \left(\frac{2}{\pi v}\right)^{\frac{1}{2}} e^{i(v+\frac{1}{2}\pi)}. \quad (2)$$

Substituting (1), (2) into (3) § 19.20 leads to the formula

$$\phi_2 \sim 2\phi_0 \left(\frac{2}{\pi k_1 r}\right)^{\frac{1}{2}} e^{i(k_1 r - \omega t + \frac{1}{2}\pi)} \sum_{m=1}^{\infty} \text{se}_m(\eta, q) \text{se}_m(\theta, q) \frac{\text{se}_m'(0, q)}{\text{Ne}_m^{(1)'}(0, q)}. \quad (3)$$

This represents the velocity potential of the scattered wave at a great distance  $r$  from the ribbon. The pressure is  $\rho_0 \partial \phi_2 / \partial t$ , so

$$p_2 = -i\rho_0 \omega \phi_2 \sim 2\rho_0 \omega \phi_0 \left(\frac{2}{\pi k_1 r}\right)^{\frac{1}{2}} e^{i(k_1 r - \omega t + \frac{1}{2}\pi)} \times \sum_{m=1}^{\infty} \text{se}_m(\eta, q) \text{se}_m(\theta, q) \frac{\text{se}_m'(0, q)}{\text{Ne}_m^{(1)'}(0, q)}. \quad (4)$$

**19.30. Scattering of electromagnetic waves by long elliptical metal cylinder.** Consider the incident wave to be plane polarized, the electric force vector being parallel to the axis  $Z'OZ$ , and let the

direction of propagation be that indicated in Fig. 47.† Assuming that the cylinder has zero resistivity, the boundary condition is that the sum of the incident and scattered waves is zero at the surface where  $\xi = \xi_0$ . For the incident plane polarized wave the electric force is represented by

$$E_1 = E_0 e^{i(k_1 \rho - \omega t)}, \quad (1)$$

so by § 19.12, in terms of elliptical coordinates we have

$$E_1 = 2e^{-i\omega t} E_0 \sum_{n=0}^{\infty} [\text{as at (3) § 19.12}]. \quad (2)$$

For the scattered wave we take

$$E_2 = \text{the r.h.s. of (3) § 19.14.} \quad (3)$$

The boundary condition is that

$$E_1 + E_2 = 0 \quad \text{when} \quad \xi = \xi_0, \quad (4)$$

so from (2), (3) we obtain

$$C_{2n} = -\frac{2E_0}{p_{2n}} \frac{C_{2n}(\xi_0)}{\text{Me}_{2n}^{(1)}(\xi_0)}, \quad C_{2n+1} = -\frac{2iE_0}{p_{2n+1}} \frac{\text{Ce}_{2n+1}(\xi_0)}{\text{Me}_{2n+1}^{(1)}(\xi_0)}; \quad (5)$$

$$S_{2n+1} = -\frac{2iE_0}{s_{2n+1}} \frac{\text{Se}_{2n+1}(\xi_0)}{\text{Ne}_{2n+1}^{(1)}(\xi_0)}, \quad S_{2n+2} = -\frac{2E_0}{s_{2n+2}} \frac{S_{2n+2}(\xi_0)}{\text{Ne}_{2n+2}^{(1)}(\xi_0)}. \quad (6)$$

Writing

$$\begin{aligned} \text{Ce}_m(\xi_0)/\text{Me}_m^{(1)}(\xi_0) &= \cos \alpha_m e^{-i\alpha_m}, \\ \cos \alpha_m &= \text{Ce}_m(\xi_0)/[\text{Ce}_m^2(\xi_0) + \text{Fe}_m^2(\xi_0)]^{\frac{1}{2}}; \end{aligned} \quad (7)$$

$$\begin{aligned} \text{Se}_m(\xi_0)/\text{Ne}_m^{(1)}(\xi_0) &= \cos \beta_m e^{-i\beta_m}, \\ \cos \beta_m &= \text{Se}_m(\xi_0)/[\text{Se}_m^2(\xi_0) + \text{Ge}_m^2(\xi_0)]^{\frac{1}{2}}, \end{aligned} \quad (8)$$

(3) may be expressed in the form

$$\begin{aligned} E_2 = & -2e^{-i\omega t} E_0 \sum_{n=0}^{\infty} \left[ \frac{A_0^{(2n)} e^{-i\alpha_{2n}} \cos \alpha_{2n} \text{Me}_{2n}^{(1)}(\xi) \text{ce}_{2n}(\eta) \text{ce}_{2n}(\theta)}{\text{ce}_{2n}(0) \text{ce}_{2n}(\frac{1}{2}\pi)} + \right. \\ & + \frac{k^2 B_2^{(2n+2)} e^{-i\beta_{2n+1}} \cos \beta_{2n+2} \text{Ne}_{2n+2}^{(1)}(\xi) \text{se}_{2n+2}(\eta) \text{se}_{2n+2}(\theta)}{\text{se}_{2n+2}'(0) \text{se}_{2n+2}'(\frac{1}{2}\pi)} + \\ & + i \left\{ \frac{-k A_1^{(2n+1)} e^{-i\alpha_{2n+1}} \cos \alpha_{2n+1} \text{Me}_{2n+1}^{(1)}(\xi) \text{ce}_{2n+1}(\eta) \text{ce}_{2n+1}(\theta)}{\text{ce}_{2n+1}(0) \text{ce}_{2n+1}'(\frac{1}{2}\pi)} + \right. \\ & \left. \left. + \frac{k B_1^{(2n+1)} e^{-i\beta_{2n+1}} \cos \beta_{2n+1} \text{Ne}_{2n+1}^{(1)}(\xi) \text{se}_{2n+1}(\eta) \text{se}_{2n+1}(\theta)}{\text{se}_{2n+1}'(0) \text{se}_{2n+1}'(\frac{1}{2}\pi)} \right\} \right]. \quad (9) \end{aligned}$$

† The equation of propagation is (11) § 18.22 in rectangular coordinates, and (1) § 18.50 in elliptical coordinates.

When  $\theta = \frac{1}{2}\pi$ ,  $\text{ce}_{2n+1}(\theta) = \text{se}_{2n+2}(\theta) = 0$ , and (3), (5), (6) yield

$$E_2 = -e^{-i\omega t} 2E_0 \sum_{n=0}^{\infty} \left[ \frac{\text{Ce}_{2n}(\xi_0)}{p_{2n} \text{Me}_{2n}^{(1)}(\xi_0)} \text{Me}_{2n}^{(1)}(\xi) \text{ce}_{2n}(\eta) \text{ce}_{2n}(\tfrac{1}{2}\pi) + \right. \\ \left. + \frac{i \text{Se}_{2n+1}(\xi_0)}{s_{2n+1} \text{Ne}_{2n+1}^{(1)}(\xi_0)} \text{Ne}_{2n+1}^{(1)}(\xi) \text{se}_{2n+1}(\eta) \text{se}_{2n+1}(\tfrac{1}{2}\pi) \right]. \quad (10)$$

If  $\xi$  is large enough,  $v = k \cosh \xi \simeq k_1 r$ , and the asymptotic forms of the Me, Ne functions may be used. Then with the dominant term only (see § 11.11)

$$\frac{2\text{Me}_{2n}^{(1)}(\xi)}{p_{2n}} \sim \frac{2i \text{Ne}_{2n+1}^{(1)}(\xi)}{s_{2n+1}} \sim -2 \left( \frac{2}{\pi k_1 r} \right)^{\frac{1}{2}} e^{i(v + \frac{1}{2}\pi)}. \quad (11)$$

Substituting from (11) into (10) leads to

$$E_2 \sim e^{-i\omega t} 2 \left( \frac{2}{\pi k_1 r} \right)^{\frac{1}{2}} e^{i(k_1 r + \frac{1}{2}\pi)} E_0 \times \\ \times \sum_{n=0}^{\infty} \left[ \frac{\text{Ce}_{2n}(\xi_0) \text{ce}_{2n}(\eta) \text{ce}_{2n}(\frac{1}{2}\pi)}{\text{Me}_{2n}^{(1)}(\xi_0)} + \frac{\text{Se}_{2n+1}(\xi_0) \text{se}_{2n+1}(\eta) \text{se}_{2n+1}(\frac{1}{2}\pi)}{\text{Ne}_{2n+1}^{(1)}(\xi_0)} \right]. \quad (12)$$

This represents the electric force due to the scattered wave at a large distance  $r$  from the axis of the cylinder. The resultant electric force at the point is  $E = E_1 + E_2$ .

**19.31. Long rigid ribbon.** Here  $\xi_0 = 0$ , so in (6) § 19.30  $S_m = 0$ , while from (5) § 19.30

$$C_{2n} = -\frac{2E_0 \text{Ce}_{2n}(0)}{p_{2n} \text{Me}_{2n}^{(1)}(0)} = -\frac{2E_0 A_0^{(2n)}}{\text{Me}_{2n}^{(1)}(0) \text{ce}_{2n}(\frac{1}{2}\pi)}$$

$$\text{and} \quad C_{2n+1} = -\frac{2iE_0 \text{Ce}_{2n+1}(0)}{p_{2n+1} \text{Me}_{2n+1}^{(1)}(0)} = \frac{2ikA_1^{(2n+1)}E_0}{\text{Me}_{2n+1}^{(1)}(0) \text{ce}_{2n+1}'(\frac{1}{2}\pi)}. \quad (1)$$

Substituting from (1) into (3) § 19.30 yields

$$E_2 = -2e^{-i\omega t} E_0 \sum_{n=0}^{\infty} \left[ \frac{A_0^{(2n)} \text{Me}_{2n}^{(1)}(\xi) \text{ce}_{2n}(\eta) \text{ce}_{2n}(\theta)}{\text{Me}_{2n}^{(1)}(0) \text{ce}_{2n}(\frac{1}{2}\pi)} - \right. \\ \left. - \frac{ikA_1^{(2n+1)} \text{Me}_{2n+1}^{(1)}(\xi) \text{ce}_{2n+1}(\eta) \text{ce}_{2n+1}(\theta)}{\text{Me}_{2n+1}^{(1)}(0) \text{ce}_{2n+1}'(\frac{1}{2}\pi)} \right]. \quad (2)$$

This represents the scattered wave at any point  $(\xi, \eta)$  on or outside the ribbon.

Polar diagrams for electromagnetic waves scattered by a ribbon

of zero resistivity and width  $2h$  for various wave-lengths (as a function of  $2h$ ) and angles of incidence are shown in Fig. 49.

The solution for the diffraction of electromagnetic waves at a slit of width  $2h$  in an infinite perfectly conducting flat sheet may be obtained by analysis akin to that which precedes. The boundary

FIG. 49. Polar diagrams for electromagnetic waves scattered by a long ribbon [144].

condition is that the electric force vanishes at the surface of the sheet. In the incident wave the electric force vector is parallel to the axis of the slit.

**19.32. Formula for large distance from ribbon.** We use the asymptotic approximations

$$\text{Me}_{2n}^{(1)}(\xi) \sim -\frac{i \text{ce}_{2n}(0) \text{ce}_{2n}(\frac{1}{2}\pi)}{A_0^{(2n)}} \left( \frac{2}{\pi k_1 r} \right)^{\frac{1}{2}} e^{i(k_1 r + \frac{1}{2}\pi)} \quad (1)$$

and 
$$\text{Me}_{2n+1}^{(1)}(\xi) \sim \frac{\text{ce}_{2n+1}(0) \text{ce}_{2n+1}'(\frac{1}{2}\pi)}{k A_1^{(2n+1)}} \left( \frac{2}{\pi k_1 r} \right)^{\frac{1}{2}} e^{i(k_1 r + \frac{1}{2}\pi)}. \quad (2)$$

Inserting these in (2) § 19.31 leads to

$$E_2 \sim 2 \left( \frac{2}{\pi k_1 r} \right)^{\frac{1}{2}} e^{i(k_1 r - \omega t + \frac{1}{2}\pi)} E_0 \sum_{m=0}^{\infty} \text{ce}_m(\eta) \text{ce}_m(\theta) \frac{\text{ce}_m(0)}{\text{Me}_m^{(1)}(0)}. \quad (3)$$

This represents the scattered wave at a great distance  $r$  from the ribbon. As in (12) § 19.30 and (2) § 19.31,  $e^{-i\omega t}$  may be a separate factor.

## APPENDIX I

### *Degenerate forms of Mathieu and modified Mathieu functions*

**1. Mathieu functions.** When the fundamental ellipse tends to a circle, by § 9.11,  $h \rightarrow 0$  and, since  $q^{\frac{1}{2}} = k = \frac{1}{2}k_1 h$ ,  $q \rightarrow 0$ . By § 3.32 all  $A_p^{(m)}$  in the series for  $ce_m(\eta, q)$  tend to zero, except that  $A_m^{(m)} \rightarrow 1$ . Hence as the eccentricity  $e \rightarrow 0$ ,  $q \rightarrow 0$  and

$$ce_m(\eta, q) \rightarrow \cos m\eta = \cos m\phi \quad (m \geq 1), \quad (1)$$

the confocal hyperbolae in Fig. 16 becoming radii of the circle, with  $\eta = \phi$ . For  $n = 0$ ,  $ce_0(\eta, 0) \rightarrow 2^{-\frac{1}{2}} = A_0^{(0)}$ . In the same way it can be shown that as  $e \rightarrow 0$ ,

$$se_m(\eta, q) \rightarrow \sin m\eta = \sin m\phi \quad (m \geq 1). \quad (2)$$

*Fractional orders.* As  $e \rightarrow 0$ ,  $q \rightarrow 0$ ,  $A_p^{(m+\beta)} \rightarrow 0$  except for  $p = m$ , when  $A_m^{(m+\beta)} \rightarrow 1$ . Thus

$$ce_{m+\beta}(z, q) \rightarrow \cos(m+\beta)\phi \quad (3)$$

and

$$se_{m+\beta}(z, q) \rightarrow \sin(m+\beta)\phi. \quad (4)$$

**2. Modified Mathieu functions.** The equation for these functions,  $q > 0$ , is

$$y'' - (a - 2k^2 \cosh 2\xi)y = 0 \quad (q = k^2). \quad (1)$$

By §§ 9.11, 9.12 when a confocal ellipse of semi-major axis  $r$  tends to a circle with this radius,  $\xi \rightarrow +\infty$ ,  $h \rightarrow 0$  such that  $h \cosh \xi \rightarrow r$ , i.e.  $\frac{1}{2}he^\xi \rightarrow r$ . Then  $2k^2 \cosh 2\xi \rightarrow k^2 e^{2\xi}$ , while if this remains finite,  $k \rightarrow 0$  and, therefore,  $a \rightarrow m^2$  for a function of integral order  $m$ . Consequently (1) degenerates to

$$y'' + (k^2 e^{2\xi} - m^2)y = 0. \quad (2)$$

Putting  $r = \frac{1}{2}he^\xi$ ,  $2k = k_1 h$ , (2) transforms to the standard Bessel equation

$$\frac{d^2 y}{dr^2} + \frac{1}{r} \frac{dy}{dr} + \left( k_1^2 - \frac{m^2}{r^2} \right) y = 0. \quad (3)$$

With  $k_1 r = ke^\xi$ , the formal solutions of (3) are  $J_m(k_1 r)$  and  $Y_m(k_1 r)$ . Then as  $\xi \rightarrow +\infty$ ,  $k \rightarrow 0$ ,  $\cosh \xi \rightarrow \sinh \xi$ ,  $k_1 r$  is finite and the solutions of (1) are constant multiples of the corresponding solutions of (3), each to each. Now as  $\xi$  and  $r \rightarrow +\infty$ , the dominant terms in the asymptotic expansions of  $Ce_m(\xi, q)$ ,  $Se_m(\xi, q)$ , and  $J_m(k_1 r)$  are identical save for constant multipliers  $p'_m$ ,  $s'_m$ . A similar remark

applies in the case of  $Fey_m(\xi, q)$ ,  $Gey_m(\xi, q)$ , and  $Y_m(k_1 r)$ . Thus we have the following degenerate cases as  $\xi \rightarrow +\infty$ :

$$Ce_m(\xi, q) \rightarrow p'_m J_m(k_1 r) \quad (m \geq 0), \quad (4)$$

$$Se_m(\xi, q) \rightarrow s'_m J_m(k_1 r) \quad (m \geq 1); \quad (5)$$

$$\frac{d}{d\xi} Ce_m(\xi, q) \rightarrow p'_m r \frac{d}{dr} J_m(k_1 r) = p'_m k_1 r J'_m(k_1 r) \quad (m \geq 0), \quad (6)$$

$$\frac{d}{d\xi} Se_m(\xi, q) \rightarrow s'_m r \frac{d}{dr} J_m(k_1 r) = s'_m k_1 r J'_m(k_1 r) \quad (m \geq 1); \quad (7)$$

$$Fey_m(\xi, q) \rightarrow p'_m Y_m(k_1 r) \quad (m \geq 0), \quad (8)$$

$$Gey_m(\xi, q) \rightarrow s'_m Y_m(k_1 r) \quad (m \geq 1); \quad (9)$$

$$\frac{d}{d\xi} Fey_m(\xi, q) \rightarrow p'_m k_1 r Y'_m(k_1 r) \quad (m \geq 0), \quad (10)$$

$$\frac{d}{d\xi} Gey_m(\xi, q) \rightarrow s'_m k_1 r Y'_m(k_1 r) \quad (m \geq 1). \quad (11)$$

Applying the foregoing to (1), (2) § 13.40 leads to

$$Me_{2n}^{(1)}(z, q) = -2i \text{Fek}_{2n}(z, q) \rightarrow p'_{2n} H_{2n}^{(1)}(k_1 r), \quad (12)$$

$$Me_{2n+1}^{(1)}(z, q) = -2 \text{Fek}_{2n+1}(z, q) \rightarrow p'_{2n+1} H_{2n+1}^{(1)}(k_1 r); \quad (13)$$

$$Ne_{2n+1}^{(1)}(z, q) = -2 \text{Gek}_{2n+1}(z, q) \rightarrow s'_{2n+1} H_{2n+1}^{(1)}(k_1 r), \quad (14)$$

$$Ne_{2n+2}^{(1)}(z, q) = -2i \text{Gek}_{2n+2}(z, q) \rightarrow s'_{2n+2} H_{2n+2}^{(1)}(k_1 r). \quad (15)$$

The degenerate forms of  $Fe_m(z, q)$ ,  $Ge_m(z, q)$  may be derived by applying (4), (5), (8), (9) to (4), (5) § 13.21, while those of the functions of order  $(m+\beta)$  are identical in form with (4), (5), but  $m$  is replaced by  $(m+\beta)$ .

**3. Determination of  $p'_m$ ,  $s'_m$ .** These are obtained by comparing the dominant terms in the asymptotic expansions of the corresponding functions. Thus by (1) § 11.10 and (15) § 8.10, when  $\xi \rightarrow +\infty$

$$Ce_{2n}(\xi, q) \sim \frac{ce_{2n}(0, q)ce_{2n}(\frac{1}{2}\pi, q)}{A_0^{(2n)}} \left( \frac{2}{\pi k e \xi} \right)^{\frac{1}{2}} \sin(ke\xi + \frac{1}{4}\pi), \quad (1)$$

$$\text{while} \quad J_{2n}(k_1 r) \sim (-1)^n \left( \frac{2}{\pi k_1 r} \right)^{\frac{1}{2}} \sin(k_1 r + \frac{1}{4}\pi). \quad (2)$$

Remembering that as  $\xi \rightarrow +\infty$ ,  $ke\xi \rightarrow k_1 r$ , it follows from (1), (2) and (4) § 2, that

$$p'_{2n} = (-1)^n ce_{2n}(0, q)ce_{2n}(\frac{1}{2}\pi, q)/A_0^{(2n)} = (-1)^n p_{2n}. \quad (3)$$

Similarly we find that

$$p'_{2n+1} = (-1)^{n+1} \text{ce}_{2n+1}(0, q) \text{ce}'_{2n+1}(\tfrac{1}{2}\pi, q) / k A_1^{(2n+1)} = (-1)^n p_{2n+1}, \quad (4)$$

$$s'_{2n+1} = (-1)^n \text{se}'_{2n+1}(0, q) \text{se}_{2n+1}(\tfrac{1}{2}\pi, q) / k B_1^{(2n+1)} = (-1)^n s_{2n+1}, \quad (5)$$

and

$$s'_{2n+2} = (-1)^{n+1} \text{se}'_{2n+2}(0, q) \text{se}_{2n+2}(\tfrac{1}{2}\pi, q) / k^2 B_2^{(2n+2)} = (-1)^{n+1} s_{2n+2}. \quad (6)$$

**4. Results for  $q < 0$ .** We write  $-k_1^2$  for  $k_1^2$  in (3) § 2 thereby obtaining the equation for the modified Bessel functions  $I_m(k_1 r)$ ,  $K_m(k_1 r)$ . The degenerate cases are:

$$\text{Ce}_{2n}(\xi, -q) \rightarrow p'_{2n} I_{2n}(k_1 r), \quad (1)$$

$$\text{Ce}_{2n+1}(\xi, -q) \rightarrow s'_{2n+1} I_{2n+1}(k_1 r); \quad (2)$$

$$\text{Se}_{2n+1}(\xi, -q) \rightarrow p'_{2n+1} I_{2n+1}(k_1 r), \quad (3)$$

$$\text{Se}_{2n+2}(\xi, -q) \rightarrow s'_{2n+2} I_{2n+2}(k_1 r); \quad (4)$$

$$\frac{d}{d\xi} \text{Ce}_{2n}(\xi, -q) \rightarrow p'_{2n} k_1 r I'_{2n}(k_1 r), \quad (5)$$

$$\frac{d}{d\xi} \text{Ce}_{2n+1}(\xi, -q) \rightarrow s'_{2n+1} k_1 r I'_{2n+1}(k_1 r); \quad (6)$$

$$\frac{d}{d\xi} \text{Se}_{2n+1}(\xi, -q) \rightarrow p'_{2n+1} k_1 r I'_{2n+1}(k_1 r), \quad (7)$$

$$\frac{d}{d\xi} \text{Se}_{2n+2}(\xi, -q) \rightarrow s'_{2n+2} k_1 r I'_{2n+2}(k_1 r); \quad (8)$$

$$\pi \text{Fek}_{2n}(\xi, -q) \rightarrow p'_{2n} K_{2n}(k_1 r), \quad (9)$$

$$\pi \text{Fek}_{2n+1}(\xi, -q) \rightarrow s'_{2n+1} K_{2n+1}(k_1 r); \quad (10)$$

$$\pi \text{Gek}_{2n+1}(\xi, -q) \rightarrow p'_{2n+1} K_{2n+1}(k_1 r), \quad (11)$$

$$\pi \text{Gek}_{2n+2}(\xi, -q) \rightarrow s'_{2n+2} K_{2n+2}(k_1 r). \quad (12)$$

The results for  $\text{Me}_m^{(1)}(\xi, -q)$ ,  $\text{Ne}_m^{(1)}(\xi, -q)$  may be derived from (9)–(12) and § 13.41.

**5. Degeneration of  $\text{ce}_m(z, -q)$ ,  $\text{se}_m(z, -q)$  to parabolic cylinder functions.** When  $z$  is small,  $\cos 2z \simeq 1 - 2z^2$  and Mathieu's equation, for  $q$  negative, may be written

$$y'' + (a + 2q - 4qz^2)y = 0. \quad (1)$$

Let  $z = \frac{1}{2}xq^{-\frac{1}{2}}$ , and suppose that as  $q \rightarrow +\infty$ ,  $z \rightarrow 0$  but  $qx^2$  remains finite [91]. Then by (2) § 12.30,

$$(a_{2n} + 2q) \sim (8n + 2)q^{\frac{1}{2}}, \quad (2)$$

and with these changes (1) is transformed to

$$\frac{d^2y}{dx^2} + [(2n + \frac{1}{2}) - \frac{1}{4}x^2]y = 0, \quad (3)$$

which is the differential equation for the parabolic cylinder function  $D_{2n}(x)$ . Hence under the above conditions

$$ce_{2n}(z, -q) \rightarrow \text{a constant} \times D_{2n}(x) = K D_{2n}(2zq^{\frac{1}{4}}). \quad (4)$$

Similarly it may be shown that

$$se_{2n+1}(z, -q) \rightarrow \text{a constant} \times D_{2n+1}(x). \quad (5)$$

# APPENDIX II

### APPENDIX III

#### *Classification of Mathieu functions for $a, q$ real $\geq 0$*

In Tables 26-8,  $m = 2n$  or  $2n+1$ ,  $n = 0, 1, 2, \dots$ ;  $0 < \beta < 1$ ;  $\mu$  real and positive.

TABLE 26. *Solutions of  $y'' + (a - 2q \cos 2z)y = 0$ :  
ordinary functions*

Order	First kind	Second kind	Alternative second kind
Integral	$ce_m(z, \pm q)$	$fe_m(z, \pm q)$	$fek_m(z, -q), z \text{ real}$
Integral	$se_m(z, \pm q)$	$ge_m(z, \pm q)$	$gek_m(z, -q), z \text{ real}$
Fractional	$ce_{m+\beta}(z, \pm q)$	$se_{m+\beta}(z, \pm q)$	

TABLE 27. *Solutions of  $y'' - (a - 2q \cosh 2z)y = 0$ :  
modified functions*

Order	First kind	Second kind	Alternative second kind	Third kind
Integral	$Ce_m(z, \pm q)$	$Fey_m(z, \pm q); Fek_m(z, \pm q)$	$Fe_m(z, \pm q)$	$Me_m^{(1),(2)}(z, \pm q)$
Integral	$Se_m(z, \pm q)$	$Gey_m(z, \pm q); Gek_m(z, \pm q)$	$Ge_m(z, \pm q)$	$Ne_m^{(1),(2)}(z, \pm q)$
Fractional	$Ce_{m+\beta}(z, \pm q)$	$Se_{m+\beta}(z, \pm q)$		

TABLE 28. *Solutions of  $y'' + (a - 2q \cos 2z)y = 0$ :  
functions of order  $(m+\mu)$*

First kind	Second kind
$ceu_{m+\mu}(z, \pm q)$	$ceu_{m+\mu}(-z, \pm q)$

The  $ce_r$ ,  $ce_i$  functions have been omitted since  $q$  is negative imaginary.  $Fey$ ,  $Gey$ ,  $Fek$ ,  $Gek$  take priority over  $Fe_m$ ,  $Ge_m$  as modified functions of the second kind because:

1. They are better suited for applications when  $z$  is large;
2. Their representations in B.F. product series converge rapidly, thereby facilitating computation;
3. They degenerate to the  $Y$ - and  $K$ -Bessel functions under the conditions in Appendix I.

Excepting  $Fe_m$ ,  $Ge_m$ , alternative representations of each function are given herein. For instance, four different series and five integral relations are given for  $Ce_m(z, q)$ .  $Fey_m(z, q)$  is a  $Y$ -type modified Mathieu function of the second kind of order  $m$ ,  $q$  positive, whereas  $Fek_m(z, -q)$  is a  $K$ -type modified Mathieu function of the second kind of order  $m$ ,  $q$  negative.

## ADDITIONAL RESULTS

The following were obtained after the manuscript went to press. The analysis underlying the derivation of the formulae is usually omitted for brevity (see [227]).

**1. Evaluation of  $\text{Fey}'_m(0, q)/\text{Fe}'_m(0, q)$  and  $\text{Gey}_m(0, q)/\text{Ge}_m(0, q)$  in § 13.21.** By comparison it follows from (1) § 7.61, (3)–(5) § 13.20, and (3), (4) § 13.21, that for  $q$  real  $> 0$

$$B = \text{Fey}'_{2n}(0, q)/\text{Fe}'_{2n}(0, q) = 2/\pi C_{2n}(q). \quad (1)$$

Similarly  $\text{Fey}'_{2n+1}(0, q)/\text{Fe}'_{2n+1}(0, q) = 2/\pi C_{2n+1}(q), \quad (2)$

and  $\text{Gey}_m(0, q)/\text{Ge}_m(0, q) = -2/\pi S_m(q). \quad (3)$

**2. Relations between  $C'_m, C_m(q); S'_m, S_m(q)$  in §§ 13.52–13.55.** By aid of (3)–(6) § 13.52, we deduce that

$$C'_{2n} = -\frac{1}{2}\pi C_{2n}(q). \quad (1)$$

We also find that  $C'_{2n+1} = -\frac{1}{2}\pi C_{2n+1}(q), \quad (2)$

and  $S'_m = -\frac{1}{2}\pi S_m(q). \quad (3)$

From (1) § 7.22, (3) § 13.53, and (1) above, we get

$$p_{2n} \text{ce}_{2n}(\tfrac{1}{2}\pi, q)/A_0^{(2n)} = \text{ce}_{2n}(0, q) + \sum_{r=0}^{\infty} (2r+2) f_{2r+2}^{(2n)} = \text{fe}'_{2n}(0, q)/C_{2n}(q). \quad (4)$$

Also

$$\begin{aligned} -p_{2n+1} \text{ce}'_{2n+1}(\tfrac{1}{2}\pi, q)/kA_1^{(2n+1)} &= \text{ce}_{2n+1}(0, q) + \sum_{r=0}^{\infty} (2r+1) f_{2r+1}^{(2n+1)} \\ &= \text{fe}'_{2n+1}(0, q)/C_{2n+1}(q), \end{aligned} \quad (5)$$

$$s_{2n+1} \text{se}_{2n+1}(\tfrac{1}{2}\pi, q)/kB_1^{(2n+1)} = \sum_{r=0}^{\infty} g_{2r+1}^{(2n+1)} = \text{ge}_{2n+1}(0, q)/S_{2n+1}(q), \quad (6)$$

$$s_{2n+2} \text{se}'_{2n+2}(\tfrac{1}{2}\pi, q)/k^2 B_2^{(2n+2)} = \sum_{r=0}^{\infty} g_{2r}^{(2n+2)} = \text{ge}_{2n+2}(0, q)/S_{2n+2}(q). \quad (7)$$

**3. Limiting forms of  $\text{Fey}_m, \text{Gey}_m, \text{Fek}_m, \text{Gek}_m, C_m(q), S_m(q)$  as  $q \rightarrow +0$ .**

$$\left. \begin{matrix} \text{Fey} \\ 2\text{Fek} \end{matrix} \right\}_0(z, q) \rightarrow \pm \frac{2^{\frac{1}{2}}}{\pi} (z + \tfrac{1}{2} \log_e q), \quad (1, 2)$$

$$\left. \begin{matrix} \text{Fey} \\ \text{Gey} \end{matrix} \right\}_m(z, q) \rightarrow -2^{2m-1} (m-1)! m! \pi^{-1} q^{-m} e^{-mz} \quad (m \geq 1), \quad (3, 4)$$

$$\left. \begin{matrix} \text{Fek} \\ \text{Gek} \end{matrix} \right\}_m(z, -q) \rightarrow -\tfrac{1}{2} \left. \begin{matrix} \text{Fey} \\ \text{Gey} \end{matrix} \right\}_m(z, q) \quad (m \geq 1), \quad (5, 6)$$

provided  $q$  and  $ke^{\pm z}$  are small enough. The forms (1)–(6) show that the functions of zero order have a branch point, while those of higher integral order have a pole of equal order at  $q = 0$ . These formulae were derived from the B.F. product series, with the aid of (8), (9) § 3.33. Approximate representations of the  $J$ -,  $Y$ -,  $I$ -,  $K$ -Bessel functions were used, and only the dominant term in the expansion retained. More accurate formulae may be derived by retaining appropriate additional terms before and after the dominant terms. Thus

$$\left. \begin{matrix} \text{Fey} \\ 2\text{Fek} \end{matrix} \right\}_0(z, q) \simeq \pm \frac{2^{\frac{1}{2}}}{\pi} [(\gamma - \log_e 2) + \frac{1}{2} \log_e q + z] [1 \mp \frac{1}{2} q \cosh 2z], \quad (7, 8)$$

where  $(\gamma - \log_e 2) = -0.1159\dots$ , and if  $n \geq 2$ ,

$$\left. \begin{matrix} \text{Fey} \\ 2\text{Fek} \end{matrix} \right\}_{2n}(z, q) \simeq \mp \frac{2^{4n-1}(2n-1)!(2n)!e^{-2nz}}{\pi q^{2n}} \times \left\{ 1 \pm \frac{1}{2} q \left[ \frac{e^{2z}}{(2n-1)} - \frac{e^{-2z}}{(2n+1)} \right] \right\}. \quad (9, 10)$$

When the order of the function  $m \geq 1$ , the multipliers  $p_{2n}/A_0^{(2n)}$ ,  $p_{2n+1}/A_1^{(2n+1)}$ , etc. (see Appendix I), external to the B.F. product series for these functions (see Chap. XIII), have singularities at  $q = 0$ . For example

$$\begin{aligned} & \text{Fey}_{2n+1}(z, q) \\ &= [p_{2n+1}/A_1^{(2n+1)}] \sum_{r=0}^{\infty} (-1)^r A_{2r+1}^{(2n+1)} [J_r(v_1)Y_{r+1}(v_2) + J_{r+1}(v_1)Y_r(v_2)], \end{aligned} \quad (11)$$

where  $v_1 = ke^{-z}$ , and  $v_2 = ke^z$ . As  $q \rightarrow 0$ , the multiplier

$$p_{2n+1}/A_1^{(2n+1)} \rightarrow (-1)^n 2^{4n}(2n)!(2n+1)!q^{-2n-1}, \quad (12)$$

while

$$\sum_{r=0}^{\infty} (-1)^r A_{2r+1}^{(2n+1)} [J_r(v_1)Y_{r+1}(v_2) + J_{r+1}(v_1)Y_r(v_2)] \rightarrow (-1)^{n+1} 2\pi^{-1} q^{-\frac{1}{2}} e^{-(2n+1)z}. \quad (13)$$

Hence, considered as independent functions of  $q$ , both (12), (13) have branch points at  $q = 0$ . This is true for  $\text{Gey}_{2n+1}(z, q)$  also. The  $\sum$  part in  $\text{Fey}_{2n}(z, q)$  has no singularity in  $q$ , but that of  $\text{Gey}_{2n+2}(z, q)$  has a pole of unit order.

$$\text{As } q \rightarrow 0, \quad \text{Fe}_m(z, q) \rightarrow \sinh mz, \text{ so } \text{Fe}'_m(0, q) \rightarrow m. \quad (14)$$

Thus from (3), (14),

$$\text{Fey}'_m(0, q)/\text{Fe}'_m(0, q) \rightarrow 2^{2m-1}(m-1)!m!\pi^{-1}q^{-m}, \quad (15)$$

so from (1), (2) § 1, and (15), it follows that as  $q \rightarrow 0$

$$C_m(q) \rightarrow q^m/2^{2m-2}(m-1)!m! \quad (16)$$

$$\text{Similarly, we find that } S_m(q) \xrightarrow{z} C_m(q). \quad (17)$$

**4. Fey<sub>m</sub>, Gey<sub>m</sub>, Fek<sub>m</sub>, Gek<sub>m</sub> with argument  $(z+ip\pi)$ .**

$$\left. \begin{matrix} \text{Fey} \\ \text{Gey} \end{matrix} \right\}_m(z+ip\pi, \pm q) = \left. \begin{matrix} \text{Fey} \\ \text{Gey} \end{matrix} \right\}_m(z, \pm q) + 2ip \left. \begin{matrix} \text{Ce} \\ \text{Se} \end{matrix} \right\}_m(z, \pm q), \quad (1, 2)$$

$p$  being any integer if  $m$  is even. When  $m$  is odd,  $p$  is even.

$$\left. \begin{matrix} \text{Fek} \\ \text{Gek} \end{matrix} \right\}_m(z+ip\pi, \pm q) = \left. \begin{matrix} \text{Fek} \\ \text{Gek} \end{matrix} \right\}_m(z, \pm q) - ip \left. \begin{matrix} \text{Ce} \\ \text{Se} \end{matrix} \right\}_m(z, \pm q), \quad (3, 4)$$

$p$  being any integer if  $m$  is even. When  $m$  is odd,  $p$  being even, write  $+p$  for  $-ip$  on the r.h.s. of (3), (4). These formulae illustrate the non-periodic nature of the functions. By applying (1)–(6) § 13.41 to (3), (4) above, relations for  $\text{Me}_m^{(1),(2)}(z, \pm q)$ , and  $\text{Ne}_m^{(1),(2)}(z, \pm q)$  may be derived.

**5. Integrals of the form at (9)–(12) § 9.40.**

$$\begin{aligned} \Theta_{2n}^{(p)} &= \frac{1}{\pi} \int_0^{2\pi} \text{ce}_{2n}^2(u, q) \cos 2pu \, du \\ &= \sum_{r=0}^{\frac{1}{2}(p-1)} A_{2r}^{(2n)} A_{2p-2r}^{(2n)} + \sum_{r=0}^{\infty} A_{2r}^{(2n)} A_{2p+2r}^{(2n)} \end{aligned} \quad (1)$$

$$= \frac{1}{2} [A_p^{(2n)}]^2 + \sum_{r=0}^{\frac{1}{2}(p-2)} A_{2r}^{(2n)} A_{2p-2r}^{(2n)} + \sum_{r=0}^{\infty} A_{2r}^{(2n)} A_{2p+2r}^{(2n)}, \quad (2)$$

$$\begin{aligned} \Theta_{2n+1}^{(p)} &= \frac{1}{\pi} \int_0^{2\pi} \text{ce}_{2n+1}^2(u, q) \cos 2pu \, du \\ &= \frac{1}{2} [A_p^{(2n+1)}]^2 + \sum_{r=0}^{\frac{1}{2}(p-3)} A_{2r+1}^{(2n+1)} A_{2p-2r-1}^{(2n+1)} + \sum_{r=0}^{\infty} A_{2r+1}^{(2n+1)} A_{2p+2r+1}^{(2n+1)} \end{aligned} \quad (3)$$

$$= \sum_{r=0}^{\frac{1}{2}(p-2)} A_{2r+1}^{(2n+1)} A_{2p-2r-1}^{(2n+1)} + \sum_{r=0}^{\infty} A_{2r+1}^{(2n+1)} A_{2p+2r+1}^{(2n+1)}, \quad (4)$$

$$\begin{aligned} \Psi_{2n+1}^{(p)} &= \frac{1}{\pi} \int_0^{2\pi} \text{se}_{2n+1}^2(u, q) \cos 2pu \, du \\ &= -\frac{1}{2} [B_p^{(2n+1)}]^2 - \sum_{r=0}^{\frac{1}{2}(p-3)} B_{2r+1}^{(2n+1)} B_{2p-2r-1}^{(2n+1)} + \sum_{r=0}^{\infty} B_{2r+1}^{(2n+1)} B_{2p+2r+1}^{(2n+1)} \end{aligned} \quad (5)$$

$$= -\sum_{r=0}^{\frac{1}{2}(p-2)} B_{2r+1}^{(2n+1)} B_{2p-2r-1}^{(2n+1)} + \sum_{r=0}^{\infty} B_{2r+1}^{(2n+1)} B_{2p+2r+1}^{(2n+1)}, \quad (6)$$

$$\begin{aligned}
 \Psi_{2n+2}^{(p)} &= \frac{1}{\pi} \int_0^{2\pi} \text{se}_{2n+2}^2(u, q) \cos 2pu \, du \\
 &= -\frac{1}{2} \sum_{r=0}^{(p-3)} B_{2r+2}^{(2n+2)} B_{2p-2r-2}^{(2n+2)} + \sum_{r=0}^{\infty} B_{2r+2}^{(2n+2)} B_{2p+2r+2}^{(2n+2)} \quad (7) \\
 &= -\frac{1}{2} [B_p^{(2n+2)}]^2 - \sum_{r=0}^{(p-4)} B_{2r+2}^{(2n+2)} B_{2p-2r-2}^{(2n+2)} + \sum_{r=0}^{\infty} B_{2r+2}^{(2n+2)} B_{2p+2r+2}^{(2n+2)}. \quad (8)
 \end{aligned}$$

In (1), (3), (5), (7),  $p$  is an odd positive integer, while in (2), (4), (6), (8) it is even  $\geq 2$ . The results (1), (2) will enable additional terms in (5)–(7) § 18.55 to be obtained.

## 6. Improved asymptotic formulae, $q$ large and positive.

These were derived from (5) § 11.43 by writing  $iz$  for  $z$ .

$$\left. \begin{array}{l} \text{Ce} \\ \text{Fey} \end{array} \right\}_m (z, q) \sim 2C_m \gamma_m \left[ (1+x_m) \frac{\cos \chi_m \pm z_m \sin \chi_m}{\sin \chi_m} \right], \quad (1, 2)$$

$$\left. \begin{array}{l} \text{Se} \\ \text{Gey} \end{array} \right\}_{m+1} (z, q) \sim \pm 2S_{m+1} \gamma_m \left[ (1+x_m) \frac{\sin \chi_m \mp z_m \cos \chi_m}{\cos \chi_m} \right], \quad (3, 4)$$

where  $\chi_m = 2k \sinh z - (2m+1) \tan^{-1}(\tanh \frac{1}{2}z)$ ,  $\gamma_m = 2^{-m-1}(\cosh z)^{-1}$ ,  $x_m = (2m+1)/8k \cosh^2 z$ ,  $z_m = (m^2+m+1) \tanh z/8k \cosh z$ . The formulae in § 11.42 may be derived by omitting the terms in  $x_m$ ,  $z_m$  in (1)–(4). Applying (4), (7), (10), (13) § 8.14 to (1)–(4) we obtain

$$\left. \begin{array}{l} \text{Fek}_{2n} \\ \text{Gek}_{2n+1} \end{array} \right\} (z, q) \sim \frac{C_{2n}}{S_{2n+1}} \gamma_{2n} [(1+x_{2n}) e^{i(\chi_{2n} + \frac{1}{2}\pi)} + z_{2n} e^{i\chi_{2n}}], \quad (5, 6)$$

$$\left. \begin{array}{l} \text{Fek}_{2n+1} \\ \text{Gek}_{2n+2} \end{array} \right\} (z, q) \sim -\frac{C_{2n+1}}{S_{2n+2}} \gamma_{2n+1} [(1+x_{2n+1}) e^{i\chi_{2n+1}} + z_{2n+1} e^{i(\chi_{2n+1} - \frac{1}{2}\pi)}]. \quad (7, 8)$$

The real and imaginary parts in (5)–(8) are required if  $z$  is real, since  $\text{Fek}_m(z, q)$ ,  $\text{Gek}_m(z, q)$  are complex. Formulae for  $\text{Me}^{(1),(2)}(z, q)$ ,  $\text{Ne}^{(1),(2)}(z, q)$  may be derived by applying (1), (2), (4), (6) § 13.41 to (5)–(8). See comment in § 7 on accuracy. The phase angle range for all asymptotic formulae in the book is  $-\frac{1}{2}\pi < \text{phase } z < \frac{1}{2}\pi$ ,  $q$  real.

## 7. Improved asymptotic formulae, $q$ large and negative.

These were derived from § 6 by applying the appropriate relations in § 8.30.

$$\left. \begin{array}{l} \text{Ce} \\ \text{Fey} \end{array} \right\}_{2n} (z, -q) \sim C_{2n} \delta_{2n} \left[ (1-X_{2n}) \left( \frac{e^{\psi_{2n}} - ie^{-\psi_{2n}}}{ie^{\psi_{2n}} - e^{-\psi_{2n}}} \right) + Z_{2n} \left( \frac{e^{\psi_{2n}} + ie^{-\psi_{2n}}}{ie^{\psi_{2n}} + e^{-\psi_{2n}}} \right) \right], \quad (1, 2)$$

$$\left. \begin{matrix} \text{Ce} \\ \text{Fey} \end{matrix} \right\}_{2n+1}(z, -q) \sim S_{2n+1} \delta_{2n} \left[ (1 - X_{2n}) \left\{ \frac{e^{\psi_{2n}} + ie^{-\psi_{2n}}}{ie^{\psi_{2n}} + e^{-\psi_{2n}}} \right\} + Z_{2n} \left\{ \frac{e^{\psi_{2n}} - ie^{-\psi_{2n}}}{ie^{\psi_{2n}} - e^{-\psi_{2n}}} \right\} \right]. \quad (3, 4)$$

Formulae for  $\text{Se}_{2n+1}(z, -q)$ ,  $\text{Gey}_{2n+1}(z, -q)$  are given by (3), (4), respectively, if  $(2n+1)$  is written on the r.h.s. for  $2n$  and  $C_{2n+1}$  for  $S_{2n+1}$ . Those for the same functions of order  $(2n+2)$  are derived from (1), (2) by the first change, and writing  $S_{2n+2}$  for  $C_{2n}$ .

$$\text{Also} \quad \text{Fek}_{2n+1}^{2n}(z, -q) \sim \frac{C_{2n}}{S_{2n+1}} \delta_{2n} e^{-\psi_{2n}} (1 - X_{2n} - Z_{2n}), \quad (5, 6)$$

$$\text{and} \quad \text{Gek}_{2n+1}^{2n+1}(z, -q) \sim \frac{C_{2n+1}}{S_{2n+2}} \delta_{2n+1} e^{-\psi_{2n+1}} (1 - X_{2n+1} - Z_{2n+1}). \quad (7, 8)$$

In (1)–(8),

$$\psi_m = 2k \cosh z - (2m+1)y, \quad \tanh 2y = (\cosh z)^{-1},$$

$$X_m = (2m+1)/8k \sinh^2 z, \quad Z_m = (m^2+m+1) \coth z / 8k \sinh z,$$

$$\delta_m = 2^{-m-1} (\sinh z)^{-1}.$$

If  $z$  is real,  $\text{Ce}$ ,  $\text{Se}$  are real, so the imaginary part is omitted;  $\text{Fey}$ ,  $\text{Gey}$  are complex, so both real and imaginary parts are used;  $\text{Fek}$ ,  $\text{Gek}$  are real. Formulae for  $\text{Me}_m^{(1),(2)}(z, -q)$ ,  $\text{Ne}_m^{(1),(2)}(z, -q)$  may be derived by applying (1), (3), (5), (6) § 13.41 to (5)–(8). See § 11.44 for remarks on accuracy. For a given order  $m$ , and an assigned  $\begin{pmatrix} z \\ q \end{pmatrix}$ , the accuracy increases with increase in  $\begin{pmatrix} q \\ z \end{pmatrix}$ , due to reduction in the omitted terms akin to  $X_m$ ,  $Z_m$ .

**8. Approximate solution of  $y'' - (a - 2q \cosh 2z)y = 0$ ,  $q$  large and positive,  $\frac{1}{2}|1+a/2q| < 1$ .** Writing the equation in the form  $y'' + 2q(\cosh 2z - a/2q)y = 0$ , the procedure in §§ 4.82, 6.20 carried as far as  $w_2$ , leads to the second approximation

$$\frac{y_1(z)}{y_2(z)} \simeq \frac{\text{a constant}}{(\cosh 2z - a/2q)^{\frac{1}{2}}} \frac{\cos \Omega}{\sin \Omega}, \quad (1, 2)$$

where

$$\begin{aligned} \Omega = & 2k \sinh z - k \left[ h^2 \text{gd}(z) + \sum_{r=2}^{\infty} \frac{1 \cdot 3 \dots (2r-3)}{2^{r-1} r!} h^{2r} D_{2r-2} \right] + \\ & + \frac{1}{16k} [\text{gd}(z) + \frac{1}{2}(13h^2 - 6)D_2 + \frac{1}{8}h^2(115h^2 - 76)D_4 + \\ & + \frac{1}{16}h^4(77h^2 - 58)D_6 + \dots], \quad (3) \end{aligned}$$

$h^2 = \frac{1}{2}(1+a/2q)$ ,  $\text{gd}(z) = 2 \tan^{-1} e^z - \frac{1}{2}\pi$ , the gudermannian of  $z$ , and

$$D_{2r} = \frac{1 \cdot 3 \dots (2r-1)}{2 \cdot 4 \dots 2r} \left[ \text{gd}(z) + \frac{\tanh z}{\cosh z} + \dots + \frac{2 \cdot 4 \dots (2r-2)}{3 \cdot 5 \dots (2r-1)} \frac{\tanh z}{\cosh^{2r-1} z} \right].$$

(1), (2) may be used as asymptotic formulae for functions of any order  $(m+\beta)$ , provided the constant multiplier can be found. Consider  $\text{Ce}_m(z, q)$ , and  $\text{Se}_{m+1}(z, q)$ . When  $q \rightarrow +\infty$ , by (7) § 12.30,  $a \sim -2q + (4m+2)k$ , so  $(\cosh 2z - a/2q)^{\frac{1}{2}} \sim 2^{\frac{1}{2}} \cosh^{\frac{1}{2}} z$ , and

$$\Omega \sim 2k \sinh z - (2m+1)\frac{1}{4}\pi.$$

Thus (1), (2) give

$$\begin{aligned} y_1(z) &\sim 2^{-\frac{1}{2}} (\cosh z)^{-\frac{1}{2}} \frac{K_1 \cos}{K_2 \sin} [2k \sinh z - (2m+1)\frac{1}{4}\pi]. \end{aligned} \quad (4, 5)$$

These are the forms at (3), (4) § 11.42, if  $\tanh \frac{1}{2}z \simeq 1$ . Hence by comparison,  $K_1 = C_m/2^{m-\frac{1}{2}}$ ,  $K_2 = S_{m+1}/2^{m-\frac{1}{2}}$ . With the aid of (1)-(4) § 6, we infer that

$$\left. \begin{array}{l} \text{Ce} \\ \text{Fey} \end{array} \right\}_m (z, q) \sim \frac{C_m}{2^{m-\frac{1}{2}} (\cosh 2z - a/2q)^{\frac{1}{2}}} \frac{\cos \Omega}{\sin \Omega} \quad (a = a_m), \quad (6, 7)$$

and  $\left. \begin{array}{l} \text{Se} \\ \text{Gey} \end{array} \right\}_{m+1} (z, q) \sim \frac{\pm S_{m+1}}{2^{m-\frac{1}{2}} (\cosh 2z - a/2q)^{\frac{1}{2}}} \frac{\sin \Omega}{\cos \Omega} \quad (a = b_{m+1}). \quad (8, 9)$

**9. Parametric zeros of  $\text{Fey}_m(z, q)$ ,  $\text{Gey}_{m+1}(z, q)$ .** Applying the procedure in § 12.41 to the dominant terms in (2), (4) § 6, it is found that the formulae for  $\text{Fey}_m$ ,  $\text{Gey}_{m+1}$  are those for  $\text{Se}_{m+1}$ ,  $\text{Ce}_m$ , each to each.

## 10. Pulsatance equations for elliptical ring membrane.

Referring to § 16.11 et seq., the membrane is clamped at two confocal ellipses where  $\xi = \xi_0$  at the outer, and  $\xi = \xi_1$  at the inner. The two forms of component solution are

$$\zeta_m = [C_m \text{Ce}_m(\xi, q) + F_m \text{Fey}_m(\xi, q)] \text{ce}_m(\eta, q) \cos(\omega_m t + \epsilon_m) \quad (a_m), \quad (1)$$

and

$$\zeta_m = [S_m \text{Se}_m(\xi, q) + G_m \text{Gey}_m(\xi, q)] \text{se}_m(\eta, q) \cos(\bar{\omega}_m t + \bar{\epsilon}_m) \quad (b_m). \quad (2)$$

Inserting the boundary conditions in (1), (2) leads to the pulsatance equations

$$\text{Ce}_m(\xi_0, q) \text{Fey}_m(\xi_1, q) - \text{Ce}_m(\xi_1, q) \text{Fey}_m(\xi_0, q) = 0 \quad (m \geq 0), \quad (3)$$

and

$$\text{Se}_m(\xi_0, q) \text{Gey}_m(\xi_1, q) - \text{Se}_m(\xi_1, q) \text{Gey}_m(\xi_0, q) = 0 \quad (m \geq 1). \quad (4)$$

If  $q$  is a parametric zero of (3), (4), the corresponding nodal hyperbolae are determined, respectively, by

$$\text{ce}_m(\eta, q) = 0, \quad \text{and} \quad \text{se}_m(\eta, q) = 0. \quad (m \geq 1) \quad (5)$$

For an elliptical ring lake (see § 16.20 et seq.), the pulsance equations are obtained from (3), (4) by using the first derivatives of  $\text{Ce}_m$ ,  $\text{Fey}_m$ , etc., with respect to  $\xi$ . Nodal hyperbolae are determined by (5), using the parametric zeros of the new pulsance equations. Putting the leading terms of (1), (2) § 6 in (3), the parametric zeros are

$$q_{m,p} = k_{m,p}^2 \simeq [p\pi + \theta_m^{(0)} - \theta_m^{(1)}]^2 / 4(\sinh \xi_0 - \sinh \xi_1)^2, \quad (6)$$

with  $\theta_m^{(r)} = (2m+1)\tan^{-1}(\tanh \frac{1}{2}\xi_r)$ ,  $p$  integral  $\geq 1$ . A similar formula may be derived for (4).

**11. Formulae for  $\text{ce}_{2n}(\frac{1}{2}\pi, q)/A_0^{(2n)}$ ,  $\text{ce}_{2n}(0, q)/A_0^{(2n)}$ .** From (17) § 8.10 and (3) § 13.11

$$\text{ce}_{2n}(\tfrac{1}{2}\pi, q)/A_0^{(2n)} = \sum_{r=0}^{\infty} A_{2r}^{(2n)} J_{2r}(2k \sinh z) \Big/ \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} J_r(ke^{-z}) J_r(ke^z), \quad (1)$$

and from (15) § 8.10, (3) § 13.11

$$\begin{aligned} & \text{ce}_{2n}(0, q)/A_0^{(2n)} \\ &= \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} J_{2r}(2k \cosh z) \Big/ \sum_{r=0}^{\infty} (-1)^r A_{2r}^{(2n)} J_r(ke^{-z}) J_r(ke^z). \end{aligned} \quad (2)$$

If  $k$  is finite and  $> 0$ , these formulae are valid for all values of  $z$  except those when the numerator and denominator vanish (zeros of  $\text{Ce}_{2n}(z, q)$ ). Similar formulae may be derived for other multipliers in Chap. VIII. They may be used to calculate  $\lambda_{2n}$ , etc., on p. 185.

**12. Bessel function series for  $\text{Ce}_{m+\beta}(z, \pm q)$ ,  $\text{Se}_{m+\beta}(z, \pm q)$ .** Using analysis of the type in §§ 8.10, 8.13, we get

$$\text{Ce}_{2n+\beta}(z, q) = C_{2n+\beta} \sum_{r=-\infty}^{\infty} (-1)^r A_{2r}^{(2n+\beta)} J_{2r+\beta}(2k \cosh z), \quad (1)$$

and

$$\text{Se}_{2n+\beta}(z, q) = S_{2n+\beta} \tanh z \sum_{r=-\infty}^{\infty} (-1)^r (2r+\beta) A_{2r}^{(2n+\beta)} J_{2r+\beta}(2k \cosh z), \quad (2)$$

with

$$C_{2n+\beta} = \text{Ce}_{2n+\beta}(z_0, q) \Big/ \sum_{r=-\infty}^{\infty} (-1)^r A_{2r}^{(2n+\beta)} J_{2r+\beta}(2k \cosh z_0); \quad (3)$$

$$S_{2n+\beta} = \text{Se}_{2n+\beta}(z_0, q) \Big/ \tanh z_0 \sum_{r=-\infty}^{\infty} (-1)^r (2r+\beta) A_{2r}^{(2n+\beta)} J_{2r+\beta}(2k \cosh z_0). \quad (4)$$

In these formulae  $|\cosh z| > 1$ ,  $z_0$  is neither imaginary nor zero, and  $k$  is finite  $> 0$ .

The r.h.s. of (1) has the following properties: (a) It is even in  $z$ ; (b) it has a branch point in the  $u$ -plane ( $u = 2k \cosh z$ ) at the origin, and in the  $z$ -plane at  $z = (2r+1)\frac{1}{2}\pi i$ ,  $r = -\infty$  to  $+\infty$ , i.e. on the imaginary axis; (c) it is multivalued, and if  $\beta = p/s$ , a rational fraction in its lowest terms, it may be shown to have period  $2s\pi i$  in  $z$ ; (d) it is absolutely and uniformly convergent if  $|\cosh z| > 1$ , but non-uniformly convergent as  $|\cosh z| \rightarrow 1$ . On the imaginary axis it diverges, i.e. when  $|\cosh z| \leq 1$ . Hence there are no representations of the type (1), (2) for  $\text{ce}_{m+\beta}(z, q)$ ,  $\text{se}_{m+\beta}(z, q)$ .

$$\text{Ce}_{2n+\beta}(z, q) = \sum_{r=-\infty}^{\infty} A_{2r}^{(2n+\beta)} \cosh(2r+\beta)z$$

is analytic except at infinity where it has an essential singularity. This series and that at (1) § 13.12 in B.F. products are analytical continuations of (1) when  $|\cosh z| \leq 1$ . Series (2) has properties (b)-(d), but is odd in  $z$ .

For  $q < 0$ ,

$$\text{Ce}_{2n+\beta}(z, -q) = \bar{C}_{2n+\beta} \sum_{r=-\infty}^{\infty} (-1)^r A_{2r}^{(2n+\beta)} I_{2r+\beta}(2k \cosh z), \quad (5)$$

and

$$\text{Se}_{2n+\beta}(z, -q) = \bar{S}_{2n+\beta} \tanh z \sum_{r=-\infty}^{\infty} (-1)^r (2r+\beta) A_{2r}^{(2n+\beta)} I_{2r+\beta}(2k \cosh z), \quad (6)$$

with

$$\bar{C}_{2n+\beta} = \text{Ce}_{2n+\beta}(z_0, -q) \Big/ \sum_{r=-\infty}^{\infty} (-1)^r A_{2r}^{(2n+\beta)} I_{2r+\beta}(2k \cosh z_0); \quad (7)$$

$$\bar{S}_{2n+\beta} = \text{Se}_{2n+\beta}(z_0, -q) \Big/ \tanh z_0 \sum_{r=-\infty}^{\infty} (-1)^r (2r+\beta) \times \\ \times A_{2r}^{(2n+\beta)} I_{2r+\beta}(2k \cosh z_0), \quad (8)$$

$z_0$  as above. (5), (6) have the same properties as (1), (2) respectively. Here and in §§ 13-16, the representations for functions of order  $(2n+1+\beta)$  are obtained by writing  $(1+\beta)$  for  $\beta$ , and using  $A_{2r+1}^{(2n+1+\beta)}$  for  $A_{2r}^{(2n+\beta)}$ . (5), (6) were derived from (1), (2) by putting  $ik$  for  $k$  (by virtue of the altered sign of  $q = k^2$  in the D.E.) and writing  $(-1)^r A_{2r}^{(2n+\beta)}$  for  $A_{2r}^{(2n+\beta)}$  in accordance with § 21.

### 13. Bessel function product series for $\text{ce}_{m+\beta}(z, \pm q)$ , $\text{se}_{m+\beta}(z, \pm q)$ ,

$\text{Ce}_{m+\beta}(z, -q)$ ,  $\text{Se}_{m+\beta}(z, -q)$ .

$$\left. \begin{array}{l} \text{ce} \\ \text{se} \end{array} \right\}_{2n+\beta} (z, q) = \frac{K_{2n+\beta}}{i \bar{K}_{2n+\beta}} \sum_{r=-\infty}^{\infty} (-1)^r A_{2r}^{(2n+\beta)} [J_r(v'_1) J_{r+\beta}(v'_2) \pm J_{r+\beta}(v'_1) J_r(v'_2)], \quad (1, 2)$$

with  $v'_1 = ke^{iz}$ ,  $v'_2 = ke^{-iz}$ , the  $K$  being defined at (2), (3) § 13.12.

$$\left. \begin{array}{l} \text{ce} \\ \text{se} \end{array} \right\}_{2n+\beta}(z, -q) = (-1)^n \frac{L_{2n+\beta}}{\bar{L}_{2n+\beta}} \sum_{r=-\infty}^{\infty} (-1)^r A_{2r}^{(2n+\beta)} [I_r(v'_1) I_{r+\beta}(v'_2) \pm I_{r+\beta}(v'_1) I_r(v'_2)], \quad (3, 4)$$

with

$$L_{2n+\beta} = \text{ce}_{2n+\beta}(0, -q) / 2 \sum_{r=-\infty}^{\infty} (-1)^r A_{2r}^{(2n+\beta)} I_r(k) I_{r+\beta}(k); \quad (5)$$

$$\bar{L}_{2n+\beta} = \text{se}'_{2n+\beta}(0, -q) / 2k \sum_{r=-\infty}^{\infty} (-1)^r A_{2r}^{(2n+\beta)} [I_r(k) I'_{r+\beta}(k) - I_{r+\beta}(k) I'_r(k)]. \quad (6)$$

$$\left. \begin{array}{l} \text{Ce} \\ \text{Se} \end{array} \right\}_{2n+\beta}(z, -q) = (-1)^n \frac{L_{2n+\beta}}{\bar{L}_{2n+\beta}} \sum_{r=-\infty}^{\infty} (-1)^r A_{2r}^{(2n+\beta)} [I_r(v_1) I_{r+\beta}(v_2) \pm I_{r+\beta}(v_1) I_r(v_2)], \quad (7, 8)$$

with  $v_1 = ke^{-z}$ ,  $v_2 = ke^z$ . If  $k$  is finite and positive, (1)–(4), (7), (8) are absolutely and uniformly convergent in any finite region of the  $z$ -plane. (7), (8) are analytical continuations of (5), (6) § 12 when  $|\cosh z| \leq 1$ .

**14. Integral equations for  $\text{Ce}_{m+\beta}(z, q)$ ,  $\text{Se}_{m+\beta}(z, q)$ .** These were derived by analysis akin to that in § 10.40,

$$\text{Ce}_{2n+\beta}(z, q) = \frac{2}{\pi} C_{2n+\beta} \int_0^{\infty} \sin(2k \cosh z \cosh u - \tfrac{1}{2}\beta\pi) \text{Ce}_{2n+\beta}(u, q) du, \quad (1)$$

and

$$\begin{aligned} \text{Se}_{2n+\beta}(z, q) &= -\frac{4}{\pi} S_{2n+\beta} k \sinh z \int_0^{\infty} \cos(2k \cosh z \cosh u - \tfrac{1}{2}\beta\pi) \sinh u \text{Se}_{2n+\beta}(u, q) du, \\ &\quad (2) \end{aligned}$$

$k, z$  real  $> 0$ , while  $C_{2n+\beta}, S_{2n+\beta}$  are given at (3), (4) § 12.

**15. Asymptotic series for  $\text{Ce}_{m+\beta}(z, \pm q)$ ,  $\text{Se}_{m+\beta}(z, \pm q)$ ,  $z$  large,  $0 < \beta < 1$ .**

$$\left. \begin{array}{l} \text{Ce} \\ \text{Se} \end{array} \right\}_{2n+\beta}(z, q) \sim p_{2n+\beta}(2/\pi v)^{\frac{1}{2}} [P_{2n+\beta}^{(a)} \sin x - Q_{2n+\beta}^{(a)} \cos x], \quad (1, 2)$$

where  $p_{2n+\beta} = (-1)^n p'_{2n+\beta} = C_{2n+\beta} \text{ce}_{2n+\beta}(0, q)$ , and  $P, Q$  are given at (13), (14) § 11.20,  $a = a_{2n+\beta}$  being used to calculate the  $c$  in (7)–(9) § 11.20,  $x = v + \frac{1}{4}\pi - \frac{1}{2}\beta\pi$ ,  $v = ke^z$ ; also

$$\left. \begin{array}{l} \text{Ce} \\ \text{Se} \end{array} \right\}_{2n+\beta}(z, -q) \sim p'_{2n+\beta}(2\pi v)^{-\frac{1}{2}} \left[ e^v \sum_{r=0}^{\infty} c_r v^{-r} - i e^{-i(v+\beta\pi)} \sum_{r=0}^{\infty} (-1)^r c_r v^{-r} \right]. \quad (3, 4)$$

The functions are real if  $z$  is real, so the second member in [ ] is omitted then. If  $R(z) > 0$  is large,  $\cosh(2r+\beta)z \sim \sinh(2r+\beta)z$ , and since the coefficients  $A_{2r}^{(2n+\beta)}$  are common to the series representations of both functions (see (12) § 4.71), under the above condition they have the same asymptotic expansion.

**16. Asymptotic formulae for  $Ce_{2n+\beta}(z, q)$ ,  $Se_{2n+\beta}(z, q)$ ,  $q$  large and positive,  $0 < \beta < 1$ .**

$$\left. \begin{matrix} Ce \\ Se \end{matrix} \right\}_{2n+\beta}(z, q) \sim p_{2n+\beta}(\pi k \cosh z)^{-1} \left[ (1+x_{2n}) \frac{\cos \varphi_{2n}}{\sin \varphi_{2n-1}} \pm z_{2n} \frac{\sin \varphi_{2n}}{\cos \varphi_{2n-1}} \right], \quad (1, 2)$$

where  $\varphi_m = 2k \sinh z - \frac{1}{2}\beta\pi - (2m+1)\tan^{-1}(\tanh \frac{1}{2}z)$ ,  $x_{2n}$ ,  $z_{2n}$  are defined in § 6 and  $p_{2n+\beta}$  in § 15. See last two sentences of § 7 regarding accuracy.

**17. Degenerate forms.** Procedure akin to that in § 2 Appendix I, yields

$$\left. \begin{matrix} Ce \\ Se \end{matrix} \right\}_{m+\beta}(z, q) \rightarrow p'_{m+\beta} J_{m+\beta}(k_1 r); \quad (1, 2)$$

$$\left. \begin{matrix} Ce \\ Se \end{matrix} \right\}_m(z, -iq) \rightarrow \frac{p'_m}{s'_m} J_m(i^{\frac{1}{2}} k_1 r); \quad (3, 4)$$

## COMMENTS ON CERTAIN PARTS OF THE TEXT

**18.  $ce_m(z, q)$ ,  $se_m(z, q)$  as functions of  $q$  real  $> 0$ .** This is displayed in Figs. 167–77, pp. 288–93 in the revised American edition (1943) of *Funktionentafeln* by E. Jahnke and F. Emde. Except Figs. 167, 169, the normalization in the graphs and those of Figs. 1–4 herein is that of § 2.21. In Figs. 167, 169 the values of  $ce_0(z, q)$  have been multiplied by  $2^{\frac{1}{2}}$ . The reader should plot similar graphs using the tabular data in references 52, 95.

**19. Computation of  $\alpha, \beta, \mu$ , coefficients, etc.** The procedure in Chaps. III–VII, XIII, etc., lacks the detail usually needed by the professional computer, because the text is for the general reader. The former is able to supply the missing material required in tabulation. The general reader will find that in computing  $\beta$  or  $\mu$  (especially

the latter), the recurrence formula method in § 5.32 is easier to manipulate than the continued fractions in § 5.11. For convenience in § 5.20 et seq., we have taken  $\hat{c}_0 = 1$ , or  $c_1 = 1$ , as the case may be. When the order of the function is  $(m+\beta)$ ,  $c_0/c_m$ ,  $c_1/c_m$ , etc., may be small if  $m$  is large enough with  $q$  moderate. It might then be expedient to put  $c_m = 1$ . A similar remark applies with regard to computation of  $A_p^{(m+\beta)}$  in § 4.71, since it is proportional to  $c_p$ . For instance, if  $m = 12$ , the computation could be started at, say,  $c_{20}$  on one side of  $c_{12}$  and at  $c_4$  on the other. To reduce errors it is expedient to work *towards*  $c_{12}$  from each side. The whole range  $c_{20}$  to  $c_4$  or vice versa should not be covered in one direction only. An overlap to  $c_{m+4}$  on one side of  $c_m$ , and to  $c_{m-4}$  on the other, provides a check.

**20. Stability of solutions.** In (b) § 4.14, a solution which tends to zero as  $z \rightarrow +\infty$  is defined to be stable, although  $(a, q)$  lies in an *unstable* region of the plane. But the same solution tends to  $\pm\infty$  as  $z \rightarrow -\infty$ , so when *the whole range of*  $z$  is considered, it is unstable. In applications where  $z$  is a multiple of the time  $t$ , which is always real and positive, it is preferable that the definition (b) § 4.14 is adopted.

**21. Changing the sign of  $q$ .** It is not always expedient to do this by writing  $(\frac{1}{2}\pi - z)$  for  $z$  in solutions of (1) § 2.10, e.g. (5), (6) § 4.71. Now the recurrence relations for  $-q$  are obtained from those for  $+q$  by writing  $(-1)^r A_{2r}^{(2n+\beta)}$ , or  $(-1)^r A_{2r+1}^{(2n+1+\beta)}$ , for  $A_{2r}^{(2n+\beta)}$ ,  $A_{2r+1}^{(2n+1+\beta)}$ , as the case may be. Thus, apart from the multiplier  $(-1)^n$ , (7), (8) § 4.71 follow immediately from (1), (2) § 4.71 if this change is made. The same artifice may be used in §§ 5.20, 5.21, 5.310 to obtain solutions for a changed sign of  $q$ . When the argument in the series is  $2k \cosh z$ , it is also necessary to write  $ik$  for  $k$ , since  $(ik)^2 = -q$ . If the external multiplier is a function of  $q$ , it should be re-determined (see § 12, where (5), (6) were derived from (1), (2) in this way).

**22. Solution of (8) § 4.80.** This linear difference equation is satisfied by the  $J$ - and the  $Y$ -Bessel functions. Referring to § 3.21, if we put  $v_r = c_{r+1}/c_r$ , we obtain

$$v_{r+1} + v_r^{-1} = 4(a^{\frac{1}{2}}/q)(r+1). \quad (1)$$

Then if  $a, q$  are finite, it follows from (1) that  $v_r \rightarrow 0$  or to  $\pm\infty$  as  $r \rightarrow \pm\infty$ . Hence one solution tends to zero, the other to infinity as  $r \rightarrow \pm\infty$ . Now  $J_r \rightarrow 0$ , while by aid of (2) 1° § 8.50 it may be shown that  $Y_r \rightarrow \mp\infty$ . But for convergence of (5) § 4.80,  $c_r \rightarrow 0$ , so the  $Y$ -Bessel function is an inadmissible solution.

**23. Second solutions.** Herein we have taken the first solutions of the various differential equations to be either odd or even, according to the value of  $a$ . If the first solution is *even*, there is one (and only one) linearly independent *odd* solution, and vice versa. But by virtue of the theory of linear D.E., we may construct from these two solutions as many other second solutions as we please, which are neither odd nor even. Thus if  $Ce_m(z, q)$  is the first and even solution, the second and *odd* linearly independent solution is  $Fe_m(z, q)$  in § 7.61. If  $\gamma$  and  $\delta$  are *any* non-zero constants,

$$y_2(z) = \gamma Ce_m(z, q) + \delta Fe_m(z, q) \quad (1)$$

represents an infinite family of linearly independent second solutions, which are neither odd nor even. Now it may happen that the most suitable second solution is obtained when  $\gamma$  and  $\delta$  have special values. It is demonstrated in §§ 8.11, 8.12, 13.20 that  $Fey_m(z, q)$  is a linearly independent solution of the same D.E. as  $Ce_m(z, q)$ , and by §§ 13.20, 13.21 it has the form at (1). In this instance the values of  $\gamma, \delta$  derived in § 13.21, are fixed automatically, i.e. they are not arbitrary.  $Fey_m(z, q)$  is more suitable as a standard second solution than  $Fe_m(z, q)$ —see analysis in Chaps. VIII, X, XI, XIII, and Appendix III.

Referring to § 9.30,  $Fey_m(z, q)$ ,  $Fek_m(z, -q)$  are preferable to  $Fe_m(z, \pm q)$  in applications. They both tend to zero as  $z \rightarrow +\infty$ .

*Fundamental system.* Any two linearly independent solutions of a Mathieu equation constitute a fundamental system, since the Wronskian relation is non-zero (see (1) § 2.191). In the text it is stated sometimes that if  $y_1(z)$ ,  $y_2(z)$  are solutions satisfying this condition, while  $A, B$  are *arbitrary* constants,

$$y(z) = Ay_1(z) + By_2(z) \quad (2)$$

constitutes a fundamental system. This may be regarded as an extension of the usual definition.

**24. Formula (1) § 5.15 for  $\beta$ .** If in Fig. 11,  $a^\dagger$  is plotted instead of  $a$ , the iso- $\beta$  curves  $\beta = 0.1, 0.2, 0.3, \dots$  will intersect the  $a^\dagger$  axis at equal intervals. Provided  $|q|$  is not too large, these curves are almost parallel to the  $q$ -axis. The  $|q|$  range of parallelism increases with increase in  $a^\dagger$ , as will be evident from the last sentence of § 2.151. Then interpolation for  $\beta$  is almost linear in  $a^\dagger$ , and the accuracy of (1) § 5.15 and (4) § 4.74 will be of the same order. This is the basis

of (1) § 5.15, which is easily established by aid of paragraph one in § 5.13. In Fig. 11 for values of  $q > 0$  beyond the maxima of the iso- $\beta$  curves, where they begin to approach each other, the accuracy of (1) § 5.15 is likely to be low.

**25. Remark on (4) § 7.40 in relation to § 7.50 et seq.** By § 3.21, if  $q$  is finite, as  $r \rightarrow +\infty$ ,  $|A_{2r+3}/A_{2r+1}| \sim q/(2r+3)^2$ . Thus the r.h.s. of (4) § 7.40 is very small when  $r$  is large enough, and we get (approximately) (1) § 7.50 but with  $f$  for  $c$ . One solution tends to zero, the other to infinity as  $r \rightarrow +\infty$ . Consequently, if we *assume* that  $f_{2r-1} > f_{2r+1} > f_{2r+3}$ , etc., in (4) § 7.40, and calculate the  $f_p^{(m)}$  on this basis, we obtain a particular solution which tends to zero as  $r \rightarrow +\infty$ . The series involving the  $f_p^{(m)}$  may now be shown to have the convergence properties deduced in §§ 3.21, 3.22. The coefficients  $g_p^{(m)}$  may be treated similarly.

**26. Convergence.** Throughout the book, except perhaps at (2) 3° § 8.50,  $q$  is assumed to be finite. In fact  $q > 0$  may usually be interpreted to mean that  $q$  is greater than zero, but *finite*. When  $q \rightarrow +\infty$  an explicit statement is made to this effect.

**27. Relationships between  $Fey_m$ ,  $Ce_m$ ,  $Fek_m$ , etc. in §§ 8.14, 8.30.** These were deduced using series for  $Fey_m$ ,  $Fek_m$ , convergent only if  $|\cosh z| > 1$ . But by virtue of the B.F. product representations these functions are continuous when  $|\cosh z| \leq 1$ , so by analytical continuation the said relations are valid in any finite region of the  $z$ -plane. They may, of course, be derived directly from the B.F. product series. In view of the frequent occurrence of the foregoing restriction on  $z$ , it is apposite to remark that the 'forbidden neighbourhood' is the imaginary axis!

**28. Remark on § 10.40.** The functions represented by the r.h.s. of (4), (6), (7), (9) appear to be even in  $z$ , while those in (11), (13), (14), (16) appear to be odd. They are, however, neither odd nor even, and this point is covered by the restrictions on  $z$  at the end of the section.

 — pulsance, for elliptical lake, 302.  
 — — — membrane, 297.  
 — — — plate, 311.  
 evaluation of  $Fey_m'(0, q), Gey_m(0, q), Fek_m(0, q), Gek_m(0, q)$ , 249, 250.  
 — — miscellaneous integrals, 259-66.  
 E-waves in circular wave guide, 346.  
 — in elliptical wave guide, 349.  
 — in rectangular wave guide, 338.  
 expansion of function in terms of  $ce_m, Ce_m, se_m, Se_m$ , 297, 302.  
 — — nucleus in characteristic functions, 207.  
 $fe_m$ , characteristic number, 144.  
 — classification, 372.  
 — definition, 144.  
 — expansion in Bessel function product series, 254-6.  
 — limiting form as  $q \rightarrow 0$ , 144.  
 — non-periodic nature of, 141-3.  
 — normalization, 144, 153.  
 — recurrence formulae for coefficients in series, 148.  
 — solution of Mathieu's equation, 145.  
 $Fe_m$ , characteristic number, 155-7.  
 — classification, 372.  
 — definition, 155-7.  
 — limiting form as  $q \rightarrow 0$ , 156.  
 — normalization, 144, 153.  
 — recurrence formulae for coefficients in series, 148.  
 — relation between  $Ce_m, Fey_m$ , and, 247.  
 $fek_m$ , classification, 372.  
 — definition, 256.  
 $Fek_m$ , asymptotic formula, 220-4.

- $\text{Fek}_m$ , characteristic number, 163-6.  
 — classification, 372.  
 — degenerate form, 368, 369.  
 — expansion in Bessel function product series, 247, 248.  
 — — — — series, 163.  
 — non-periodic nature, 163.  
 — relation between  $\text{Ce}_m$ ,  $\text{Fey}_m$ , and, 163-6.  
 $\text{Fey}_m$ , asymptotic formula, 220-6.  
 — characteristic number, 160, 165, 166.  
 — classification, 372.  
 — degenerate form, 368.  
 — expansion in Bessel function product series, 246, 247.  
 — — — — series, 159, 161.  
 — non-periodic nature, 160.  
 — relations between  $\text{Ce}_m$ ,  $\text{Fe}_m$ , and, 247.  
 — — — —  $\text{Fek}_m$ , and, 163.  
 fluid, vortex motion in, 313-19.  
 flux, magnetic in elliptical metal core of solenoid, 322.  
 $f_m(z, q)$ , definition, 143.  
 — limiting form when  $q \rightarrow 0$ , 143, 144.  
 — normalization, 144.  
 — period, 144.  
 formula, asymptotic, *see under* asymptotic.  
 — for  $\beta$  in terms of  $a, q$ , 83.  
 $f_p^{(m)}$ , behaviour of when  $q \rightarrow 0$ , 149, 150.  
 — coefficients in series for  $\text{fe}_m$ ,  $\text{ge}_m$ ,  $\text{Fe}_m$ ,  $\text{Ge}_m$ , 144, 154-7.  
 — computation of, 150-4.  
 — recurrence relations for, 148.  
 fractional order, functions of, 19, 20, 79, 80.  
 — — — of, classification, 372.  
 frequency modulation, 6, 9, 273-82.  
  
 $\text{ge}_m$ , *see under*  $\text{fe}_m$ .  
 $\text{Ge}_m$ , *see under*  $\text{Fe}_m$ .  
 $\text{gek}_m$ , *see under*  $\text{fek}_m$ .  
 $\text{Gek}_m$ , *see under*  $\text{Fek}_m$ .  
 general relationships between solutions of Mathieu's equation, 66.  
 — solutions of Mathieu's equation, 59-64.  
 — — — — alternative form, 70-6.  
 — theory of Mathieu's equation, 57.  
 $\text{Gey}_m$ , *see under*  $\text{Fey}_m$ .  
 $g_m(z, q)$ , *see under*  $f_m(z, q)$ .  
 $g_p^{(m)}$ , *see under*  $f_p^{(m)}$ .  
 guide, wave, circular, 344-7.  
 — — elliptical, 347-51.  
 — — rectangular, 337-41.  
  
 heat conduction, *see under* conduction.  
  
 Hill's equation, 2, 4, 127.  
 — — calculation of  $\mu$ , 136.  
 — — solution of, 127, 131-5.  
 — — stability of solutions, 140.  
 — infinite determinant, 128.  
 H-waves in circular wave guide, 346.  
 — in elliptical wave guide, 349.  
 — in rectangular wave guide, 339.  
  
 identity, a fundamental, 23.  
 — integral, 265.  
 'imaginary' power in electrical circuit, 323.  
 inductance of solenoid with elliptical metal core, 323, 332.  
 infinite continued fraction for  $a$ , 29.  
 — — — convergence of, 29, 33.  
 — — — for  $v_p$ , 33.  
 — determinant, 67, 128.  
 initial conditions, 57.  
 — value problems, 9.  
 integral equation, characteristic value, 185.  
 — — definition, 178.  
 — — for  $\text{ce}_m$ , 180-4.  
 — — for  $\text{Ce}_m$ , 187-92, 197.  
 — — for  $\text{Fek}_m$ ,  $\text{Gek}_m$ , 191.  
 — — for  $\text{Fey}_m$ ,  $\text{Gey}_m$ , 190, 196.  
 — — for  $\text{se}_m$ , 180, 183-7.  
 — — for  $\text{Se}_m$ , 188, 191, 194, 198.  
 — — for  $y_1(z)y_2(z)$ ,  
 — — nuclei for, 180, 190, 191.  
 — — of first kind, 179.  
 — — of second kind, 211.  
 — — solution of, 213-16.  
 — order functions, classification, 372.  
 — relations, 186, 197-200.  
 integrals, miscellaneous, involving Mathieu functions, 259-66.  
 integro-differential equation, 214.  
 interpolation for  $a$ , 35.  
 — for  $\beta$ , 109.  
 inverse capacitance modulation, 276.  
 irrotational fluid motion, 313.  
 iso- $\beta$  curves, 79.  
 —  $-\mu$  curves, 87.  
  
 lake, circular, modes of oscillation, 303.  
 — elliptical, eccentricity  $e \rightarrow 1$ , 305.  
 — — modes of oscillation, 301.  
 limiting form of  $A_p^{(m)}$ ,  $B_p^{(m)}$  as  $q \rightarrow 0$ , 45-7.  
 — — of  $A_p^{(m+\beta)}$  as  $\beta \rightarrow 0$ , 81.  
 — — as  $q \rightarrow 0$ , 82.  
 — — of  $\text{ce}_m$ ,  $\text{se}_m$  as  $q \rightarrow 0$ , 10.  
 — — of  $\text{Ce}_m$ ,  $\text{Se}_m$  as  $q \rightarrow 0$ , 27.  
 — — of  $\text{ce}_{m+\beta}$ ,  $\text{se}_{m+\beta}$  as  $q \rightarrow 0$ , 82.

limiting form of  $fe_m, ge_m$  as  $q \rightarrow 0$ , 144.  
 — — of  $Fe_m, Ge_m$  as  $q \rightarrow 0$ , 156.  
 — — of  $f_p^{(m)}, g_p^{(m)}$  as  $q \rightarrow 0$ , 149.  
 — — of  $\rho_m$  as  $\mu \rightarrow 0$ , 89.  
 linear damping, dynamical system having, 287.  
 lines of electric and magnetic force in wave guides, 340, 348, 350.  
 line spectrum in frequency modulation, 279.  
 long rigid ribbon, scattering of e.m. waves by, 363.  
 — — scattering of sound waves by, 362.  
 loud-speaker, amplitude distortion in, 267.  
 — electromechanical rectification, 272.  
 — pulsance multiplication, 273.  
 lunar perigee, 2, 129, 130, 136.  
 $\mu$ , curves of constant, 87, 98.  
 Maclaurin series solution of Mathieu's equation, 74.  
 Mathieu functions of first, second, third kinds, 372.  
 Maxwell's equations, 334-6.  
 — application to wave guides, 338-9, 342-4.  
 $(m+\beta)$ , functions of order, 19, 20, 79, 80.  
 — — classification, 372.  
 Melde's experiment, 2, 289.  
 $Me_m^{(1),(2)}$ , application in wave propagation, 360-6.  
 — asymptotic formula, 220, 223, 225.  
 — definition, 250.  
 — degenerate form, 368, 369.  
 — expansions in Bessel function series, 250.  
 — relationship between  $Fek_m$  and, 251.  
 membrane, circular, 298, 299.  
 — elliptical, 294-8.  
 microphone, condenser type, 276.  
 $(m+\mu)$ , functions of order, 88-9.  
 — — classification, 372.  
 modified Mathieu equation, 1, 26.  
 — — functions, definition, 1, 26-7.  
 modulation, frequency, classification, 274-6.  
 — — stability chart, 277.  
 — — zones, 276.  
 $Ne_m^{(1),(2)}$ , *see under*  $Me_m^{(1),(2)}$ .  
 nodal ellipses and hyperbolae, 5, 297, 304, 307, 311-12.  
 non-linear D.E. for vibrating string, 290.  
 non-periodic solutions of Mathieu's equation, 9, 141.

normalization of  $ce_m, se_m, Ce_m, Se_m$ , 24.  
 — —  $ce_{m+\beta}, se_{m+\beta}, Ce_{m+\beta}, Se_{m+\beta}$ , 82.  
 — —  $ceu_{m+\mu}$ , 89.  
 — —  $fe_m, ge_m, Fe_m, Ge_m$ , 144, 153.  
 nuclei for integral equations, 180, 190-1.  
 — skew-symmetrical, 190, Table 17.  
 numerical solution of equations, 111-26.  
 orthogonality of  $ce_m, se_m$ , 22.  
 — — application, 99, 206, 208, 321.  
 — — of  $ce_{m+p/s}, se_{m+p/s}$ , 24.  
 — — theorem for  $ce_m, Ce_m; se_m, Se_m$ , 176.  
 — — for  $ce_m, Ce_m; se_m, Se_m$ , application, 298, 329.  
 oscillation of membrane, etc., *see under* vibrational modes.  
 oscillatory circuit, constant resistance, variable capacitance, 282.  
 — — resistanceless, variable capacitance, 274.  
 — — variable resistance, constant capacitance, 284.  
 parametric point  $(a, q)$ , 63.  
 — zeros of  $Ce_m, Se_m$ , 241.  
 periodic coefficients, differential equation having, 57.  
 — mass distribution on string, 290.  
 — solutions of first kind, 11-15, 372.  
 — — of fractional order, 20, 24, 81.  
 periodically varying capacitance, resistance, *see under* oscillatory circuit.  
 — — tension of vibrating string, 289.  
 phase factor, 337.  
 — velocity, 357.  
 plane, the  $(a, q)$ , iso- $\beta$ , iso- $\mu$  curves, stable and unstable regions, 39, 76, 98.  
 plate, vibration of circular, 313.  
 — — of elliptical, 310-12.  
 $p_m, p'_m$ , the multipliers, 368-9.  
 $P_m^{(a),(b)}$ , definition, 222.  
 polar coordinates, 170, 189, 342, 344.  
 — diagrams for diffraction of e.m. and sound waves, 363, 366.  
 power, condition for transmission in circular wave guide, 345.  
 — — in elliptical wave guide, 349.  
 — — in rectangular wave guide, 338.  
 — loss in elliptical conductor carrying a.c., 326.  
 — transmitted down elliptical wave guide, calculation, 351.  
 Poynting vector, 351.  
 problem, electromagnetic, analogous to heat conduction, 331.

- pulsation equation, *see under* equation.  
 — multiplication, 273.
- $q$ ,  $a_m$ ,  $b_m$  as a function of, 39–41.  
 —  $A_p^{(m)}$ ,  $B_p^{(m)}$  as a function of, 41–8.  
 —  $\beta$ ,  $\mu$  as a function of, 83, 97, 98.  
 — negative imaginary in Mathieu's equation, 48–56, 320.  
 — real parameter in Mathieu's equation, 1, 10.  
 — zeros in,  $Ce_m$ ,  $Se_m$ ,  $Fey_m$ ,  $Gey_m$ , 241.  
 $Q_m^{(a),(b)}$ , definition, 222.
- recurrence formula for  $A_p^{(m)}$ ,  $B_p^{(m)}$ , 28.  
 — — for  $A_p^{(m+\beta)}$ ,  $\beta$ , 65.  
 — — for coefficients in asymptotic series, 221, 225.  
 — — — in unstable solutions, 83.  
 — — for  $f_p^{(m)}$ ,  $g_p^{(m)}$ , 148–9.
- relationship between  $Ce_m$ ,  $Fe_m$ ,  $Fey_m$ , 247.  
 — — —  $Fek_m$ ,  $Fey_m$ , 163, 165–6.  
 — — —  $Se_m$ ,  $Ge_m$ ,  $Gey_m$ , 247.  
 — — —  $Gek_m$ ,  $Gey_m$ , 163–4.
- resistance, rectangular metal strip to a.c., 327.  
 — effective of solenoid with circular metal core, 324.  
 — — — with elliptical metal core, 323.  
 $R_m^{(a),(b)}$ , definition, 223.
- roots (large) of  $Ce_m(z, q) = 0$ ,  $Se_m(z, q) = 0$ , in  $q$ , 241.  
 — — — in  $z$ , 241.  
 — — of  $Fey_m(z, q) = 0$ ,  $Gey_m(z, q) = 0$ , in  $z$ , 241.
- roots of infinite determinant for  $\mu$ , 69.
- scalar potential at surface of conductor, 324.
- scattering of e.m. and sound waves by elliptical cylinder, 358–66.
- second solution of Mathieu's equation, 5, 141.  
 — — — modified equation, 155–7.
- $se_m$ , *see under*  $ce_m$ .  
 $se_{m+\beta}$ , *see under*  $ce_{m+\beta}$ .  
 $Se_m$ , *see under*  $Ce_m$ .  
 $Se_{m+\beta}$ , *see under*  $Ce_{m+\beta}$ .
- separation constant, 1, 174, 337, 344.
- side bands in frequency modulation, 6, 280.
- skew-symmetrical nucleus in integral equation, 190, Table 17.
- slab, current distribution due to e.m. field, 352.
- slit, diffraction of e.m. waves at, 366.
- slit, diffraction of sound waves at, 362.  
 $s_m$ ,  $s'_m$ , the multipliers, 368–9.  
 $S'_m$ , definition, 255.  
 $S_m^{(a),(b)}$ , definition, 223.  
 $S_m(q)$ , 144–8.  
 — computation, 153.  
 — value as  $q \rightarrow 0$ , 148.
- solenoid, effective resistance and inductance with metal core, 323–4.
- solution of Mathieu's equation,  $a$  large  
 $\gg q > 0$ , 90–6.  
 — — — circular function series, 64.  
 — — — convergence, 37, 38, 90, 169, 257.  
 — — — exponential series, 58.  
 — — — form of, in different regions of  $(a, q)$ -plane, 77, 78.  
 — — — form of,  $q = 0, 10, 11, 82$ .  
 — — — in Bessel function product series, 243.  
 — — — in Bessel function series, 158.  
 — — — numerical, 111–26.  
 — — — period  $\pi$ ,  $2\pi$ , 11–16, 21.  
 — — — period  $2s\pi$ , 20, 81.  
 — — —  $q$  series, 11–16.  
 — — — relations between, 66.  
 — — — unstable region of  $(a, q)$ -plane, 99–103.
- spectrum, line, in frequency modulation, 279.
- stability chart, 4, 39–41, 97–8.  
 — of electrical circuit having constant resistance, 283.  
 — of electrical oscillations, 278.  
 — of long column, 293.  
 — of solutions of Hill's equation, 137–40.  
 — of solutions of Mathieu's equation, 59, 60.
- stream function, 314.
- string, vibrating, constant tension, 288.  
 — — — periodic mass distribution, 290.  
 — — — variation of tension, 289.
- sub-harmonic, in dynamical system, 286–7.  
 — in vibrating string, 3, 290.
- super-regenerative radio receiver, 285.
- theorem, expansions in terms of  $ce_m$ ,  $Ce_m$ ,  $se_m$ ,  $Se_m$ , 297, 302.  
 — integral equation, 178.  
 — — relation, 186.  
 — non-periodicity of second solution of Mathieu's equation, 141.  
 — orthogonality, 175.
- thermal diffusion in elliptical cylinder, 328.

- tide height in elliptical lake, 302.
- $T_m^{(a)}$ , definition, 226.
- transformation, Mathieu's equation, 25, 26.
  - — — to Riccati type, 91.
  - wave equation to elliptical coordinates, 173.
  - — — to polar coordinates, 189, 344.
- transition, elliptical to circular section, core of solenoid, 323-4, 332.
  - — — — heat diffusion, 330.
  - — — — membrane, 298-9.
  - — — — plate, 313.
  - — — — wave guide, 355.
- transverse electric and magnetic waves in circular wave guide, 346.
  - — — — in elliptical wave guide, 349.
  - — — — in rectangular wave guide, 338-9.
- vibrational modes of gas in elliptical cylinder, 308.
- ultra high-frequency transmission in wave guide, 333.
- $U_m^{(a)}$ , definition, 226.
- uniform canal, oscillation of water, 306.
- unstable regions of  $(a, q)$ -plane, 40, 41, 97, 98.
  - solutions of Mathieu's equation, 59, 60, 84-9.
  - — — — classification, 372.
  - — — — conjugate properties of coefficients, 83.
- vector, curl of, 342.
  - differential formulae, 342.
  - potential at surface of conductor, 324.
  - Poynting's, 351.
- velocity, phase, in wave guide, 357.
  - potential, sound, 358.
  - — viscous fluid flow, 314.
- vibrating system with linear damping, 287.
- vibrational modes of gas in elliptical cylinder, 308.
  - — of membrane, 296.
  - vibrational modes of plate, 309.
    - — of string with constant tension, 288.
      - — — with periodically varying mass per unit length, 290.
      - — — with periodically varying tension, 289.
    - — of water in lake, 301.
- viscosity, kinematic coefficient of, 314.
- $V_m^{(b)}$ , definition, 227.
- volume distribution of eddy currents in slab, 352.
- vorticity of fluid round elliptical cylinder, 8, 313.
- warble tone, audio, 273.
- water, oscillation in elliptical lake, 300.
  - — in uniform canal, 306.
- wave equation, 1, 9.
  - — in elliptical coordinates, 173, 301, 310, 320, 328, 347, 358.
  - — in orthogonal curvilinear coordinates, 343.
  - — in polar coordinates, 189, 344.
  - — — in rectangular (cartesian) coordinates, 1, 170, 294, 300, 308, 320, 328, 336, 337, 358.
  - guide, circular, 344.
    - — — cut-off pulsance, 345.
    - — — elliptical, 347.
    - — — — attenuation in, 354.
    - — — — cut-off pulsance, 349.
    - — — — power transmitted down, 351.
    - — — rectangular, 337.
    - — — — cut-off pulsance, 337.
- $W_m^{(b)}$ , definition, 227.
- zeros of  $A_p^{(m)}, B_p^{(m)}$ , 43-5.
  - of  $ce_m, se_m$ , 234, [96].
  - — —  $Ce_m, Se_m$  in  $q, z$ , 241.
  - — — condensation of as  $q \rightarrow +\infty$ , 238.
- $Z_0$ , multiplier for unstable solutions, 84.
- $\bar{Z}_0$ , multiplier connecting two forms of general solution, 75.
- zones, frequency modulation, 276-7.
